## ABSTRACT

An annular plate antenna with curved and rectangular slots on vertical ground plane is proposed in this thesis. The proposed antenna is composed of two types of slots (i.e. curved and rectangular slots), cut on the annular plate to operate at dual-band frequency of UHF and microwave bands for RFID applications. This antenna is designed to achieve the unidirectional beam and high-gain for RFID reader. In addition, the antenna structure is made of metallic plate with air substrate to avoid dielectric loss. The advantages of this antenna are simple structure and easy for fabrication. From the results, the simulation and measurement are agreed very well. It is implied that the proposed antenna can be used as an RFID reader antenna. Furthermore, the annular plate antenna with curved and rectangular slots on vertical ground plane is utilized as a novel RFID sensor to determine the dielectric property of material of interest, i.e., Light Weight Concrete (LWC). From the experimental results, it is found that the novel RFID sensor provides reasonably accurate results. Therefore, this thesis accomplishes the antenna that is employed in a novel RFID sensor.

# ACKNOWLEDGEMENTS

This work has been supported by Thailand Graduate Institute of Science and Technology (TGIST), National Science and Technology Development Agency (NSTDA) under contract TGIST 01-51-067.

This thesis was successful completion and smooth by assistance and support from many people as below.

In auspicious occasion, I would like to express my grateful to my advisor, Assoc. Prof. Dr. Chuwong Phongcharoenpanich, who has given guidance, helpful suggestion and encouragement. I also would like to express my gratitude to my co-advisor, Dr. Pormanong Pongpaibool at the National Electronics and Computer Technology Center (NECTEC) for her suggestion and kind support. I am particularly grateful to Assoc. Prof. Dr. Danai Torrungrueng for his fruitful suggestion and kind assistance. I also would like to express my appreciation to Prof. Dr. Monai Krairiksh, for his valuable suggestion and encouragement.

I would like to express my cordial thanks to all members in my laboratory (T103) for discussion, friendship and familiarity. I would like to particularly thank to Dr. Kittisak Phaebua and Miss Kittima Lertsakwimarn for their helpful discussion and assistance. Moreover, I also would like to cordial thank to Miss Worada Jaturonlak and her parents for her encouragement and assistance in every matter.

Finally, I am greatly indebted to my parents for their unceasing help.

Rattapong Suwalak

# CHAPTER 1

## INTRODUCTION

This chapter introduces the background of the annular plate antenna and the feasibility to identify and inspect qualities of material of interest through nondestructive testing (NDT) techniques. The literature reviews of the annular plate antenna, the NDT techniques, the objective, the scope and organization of the thesis that summarizes information of the succeeding chapters are addressed.

### 1.1 Background and Motivation

Recently, Radio Frequency Identification (RFID) system is well known for many applications such as identification, logistics, traceability and many others [1]-[2]. The RFID system consists of two parts that the first part is an interrogator, more often known as a reader, and second part is a transponder or tag as shown Fig. 1.1. In the RFID technology, a key device for transmitting and receiving signal between communication sides is antenna. The antenna designs for both readers and tags are hot issues to improve their performances. The operating frequencies are classified by their applications, such as using the ultra-high frequency and microwave bands for long range applications. In Thailand, the UHF and microwave RFID frequency bands are from 920 MHz to 925 MHz and from 2.4 GHz to 2.5 GHz, respectively [3]. The antenna at reader plays a vital role in communication between the reader and the tags. In the literature works, there are many researches involving with flat structure [4]-[6], slot and printed antennas [7]-[13]. However, all of them are designed at relatively high frequency that the printed circuit board (PCB) is used for the microstrip antenna fabrication. Moreover, these antennas have complicated structure to implement and the gain of antennas are deteriorated from the dielectric material.

To improve the performance of the RFID system hence the proposed annular plate antenna with curved and rectangular slots on vertical ground plane is designed to achieve the unidirectional beam to direct at the tag direction. Also, the high gain antenna is required for RFID reader which results in serious improvement of the communication between the tag and the reader. Therefore, the antenna structure is made of metallic plate with air substrate to avoid dielectric loss. The design procedure and simulations are performed by using CST Microwave Studio simulator based on the Finite Integration Technique (FIT).

**Figure 1.1** The general RFID system.

Furthermore, the demand for traceability to identify and inspect qualities of material products through nondestructive testing (NDT) techniques has been on the rise. Several NDT techniques, such as Radar, Capacimetry, Electrical Resistance and Ultrasonic Waves, have been extensively used [14]-[19]. Each technique however has its advantages and disadvantages, so the selection of an appropriate technique is based on the desired application. For such construction materials (CMs) as Light Weight Concrete (LWC), Mortar specimens and Concrete, a reliable NDT technique is required to evaluate their properties whether they are suitable for construction use. Therefore, the development of a reliable sensor technique to determine material quality in manufacturing and/ or material testing and inspection process is necessary. From the sensor's viewpoint, the dependency of the read range on EM properties of CMs near or in contact with tags can be employed as an approach to determine quality of CMs through their estimated dielectric constants.

RF tag performance is affected by many factors, including EM properties of objects near or in contact with tags [20], [21]. In addition, Siden et al. presented a concept by which pairs of ordinary RFID tags are exploited as remotely read moisture sensors [22]. The moisture sensing label incorporating two RFID tags is embedded in a wall, under which one of the tags is covered with a moisture absorbent material while the other is a naked tag. They are used to detect leaking water pipe connections hidden behind the walls. Additionally, the attenuation and equivalent electric parameters of brick and reinforced concrete walls are estimated [23]. Furthermore, Marrocco et al. have presented the development of very low-cost passive RFID devices capable of monitoring the features of moving objects without the need for specific sensors. Instead, the multiport tag antennas are used as a sensor since they exploit the dependency of the tag's input impedances and the radar cross section on the physical and geometrical features of a real target [24]. However, the purpose of this paper is to describe the possible classification and detection performances of multiport sensor tags in a unitary context.

In this thesis, an NDT technique, called a novel RFID sensor, operating in the UHF band of 922.5 MHz is proposed to determine quality of certain CMs through their estimated dielectric properties. Generally, the traditional RFID sensors require additional specific sensors, such as humidity, temperature, motion, light and sound sensors, to be integrated with RFID tags [25]-[27]. On the other hand, the novel RFID sensor does not require additional specific sensors to determine dielectric properties of the materials under test, thereby more convenient in fabrication and usually of lower cost. In addition, the novel RFID sensor does not require a network analyzer and other expensive accessories. The key component of the novel RFID sensor is the tag specifically designed that will be discussed in greater detail in the remained chapter.

## **1.2 Objective and Scope of the Thesis**

This thesis has proposed a determination of dielectric property of material of interest using a novel RFID sensor that the annular plate antenna with curved and rectangular slots on vertical ground plane and the specifically designed tags (SDTs) are

also proposed to utilize as the RFID reader antenna and a remotely read dielectric-property sensors, respectively. The objective and scope of the thesis are given as follows:

1. To design and analyze of the annular plate antenna with curved and rectangular slots on vertical ground plane to radiate a high-gain unidirectional beam for the RFID reader.

2. To design and analyze of the specifically designed tags (SDTs) to employ as a novel RFID sensor.

3. To apply the novel RFID sensor for determination of dielectric property of construction material products.

### **1.3 Organization of the Thesis**

As referred above that this chapter has mentioned about the overview of this thesis. The annular plate antenna with curved and rectangular slots is designed for RFID reader. Subsequently, the RFID tags are also appropriately designed called the novel RFID sensor to determine qualities of some material of interest. Moreover, the objective, scope of this thesis and organization of the thesis are summarized.

The remaining portion of this thesis consists of five chapters. They are involving theories and applications of the determination of the dielectric constant of material of interest.

Chapter 2 presents the antenna theory and design procedure of the annular plate antenna with curved and rectangular slots on vertical ground plane using the electromagnetic simulator program. In addition, the improvement of the antenna characteristics by using the optimization method in the simulator is performed to determine the optimum antenna parameters and can be applied for the RFID reader.

Chapter 3 discusses the design of RFID tags and the relation between the maximum read range and RFID tag to utilize as a novel RFID sensor for determination of the electrical characteristics of the material of interest.

Chapter 4 verifies the proposed annular plate antenna with curved and rectangular slots on the vertical ground plane that has presented in the preceding chapter by measurement. The prototype of the antenna was fabricated corresponding to the optimum parameters suggested in chapter 2. The experimental results of magnitude of  $S_{11}$ , radiation pattern and gain are performed. The measurement results are compared with the results from the simulation to verify the accuracy.

Chapter 5 mentions the experimental results of maximum read range between RFID reader and RFID sensor. In addition, the determination procedure of electrical characteristics of material under test is investigated by using the RFID technology as a sensor viewpoint.

Chapter 6 summarizes the consequence of the material presented in the preceding chapters together with the discussions for the further study.

## CHAPTER 2

# ANTENNA DESIGN

### 2.1 Introduction

This chapter presents the antenna theory and antenna design procedure using the electromagnetic simulator to obtain the appropriated antenna parameters that radiates a high-gain unidirectional pattern. The annular plate antenna with curved and rectangular slots on vertical ground plane is proposed to operate at dual-band of UHF and microwave bands of the RFID application.

### 2.2 Configuration of an Annular Plate Antenna with Curved and Rectangular Slots on Vertical Ground Plane

The antenna at reader plays a vital role in communication between the reader and the tags. The proposed annular plate antenna with curved and rectangular slots on vertical ground plane is investigated to respond the dual-band frequency of RFID systems (UHF and microwave bands) as shown in Fig. 2.1. Note that the proposed antenna is composed of two types of slots (curved and rectangular slots), cut on the annular plate to operate at the upper frequency band (microwave frequency). The antenna is designed to achieve the unidirectional beam to direct at the tag direction. Also, the high-gain antenna is required for RFID reader which results in serious improvement of the communication between the tag and the reader. Therefore, the antenna structure is made of metallic plate with air substrate to avoid dielectric loss. The simulations are performed by using CST Microwave Studio simulator based on the Finite Integration Technique (FIT).

The rest of this chapter, the antenna design procedure and antenna theory are discussed in subsequent sections. Section II presents the characteristics of the annular

plate antenna with curved and rectangular slots on vertical ground plane with the optimum parameters. Finally, brief conclusions are summarized in the last section.

**Figure 2.1** The annular plate antenna with curved and rectangular slots on vertical ground plane

### 2.3 Antenna Design Principle

The determination of the optimal structure and parameters of the antenna for the RFID reader that can be responded a dual-band frequency is separated into 4 steps as follow: the circular plate design, the annular plate design, the design of annular plate with curved and rectangular slots and finally, the design of annular plate antenna with curved and rectangular slots on vertical ground plane.

#### 2.3.1 Circular Plate Antenna

In this section, the antenna design procedures are performed that the designs begin with the lower band ( $f_L$ ) of operating frequency of 922.5 MHz. The circular plate antenna is the initial structure as shown in Fig. 2.2. Its dimensions were calculated using

the cavity model method [28]. This method is composed of two perfect electric conductors of the radiating plate and the infinite ground plane.

**Figure 2.2** A circular plate antenna

According to the cavity model consideration, the radius of the radiating circular plate ( $a$ ) for the  $TM_{mn0}^z$  mode can be expressed as

$$a = \frac{1}{2\pi\sqrt{\mu\varepsilon}} \left( \frac{\chi'_{mn}}{(f_r)_{mn0}} \right), \quad (2.1)$$

where  $\mu$  is permeability

$\varepsilon$  is permittivity

$(f_r)_{mn0}$  is resonant frequency at 922.5 MHz

$\chi'_{mn}$  is the zeroes of the derivative of the Bessel function  $J_m(x)$ .

For the dominant mode of the  $TM_{110}^z$ ,  $\chi'_{11}$  is 1.8412. Therefore, the radius of the radiating circular plate ( $a$ ) in (2.1) can be modified and written as

$$a = \frac{1.8412}{2\pi\sqrt{\varepsilon_r}} \left( \frac{v_0}{(f_r)_{110}} \right), \quad (2.2)$$

where  $v_0$  is the speed of light in free-space of  $3 \times 10^8$  m/s

$\varepsilon_r$  is the relative permittivity.

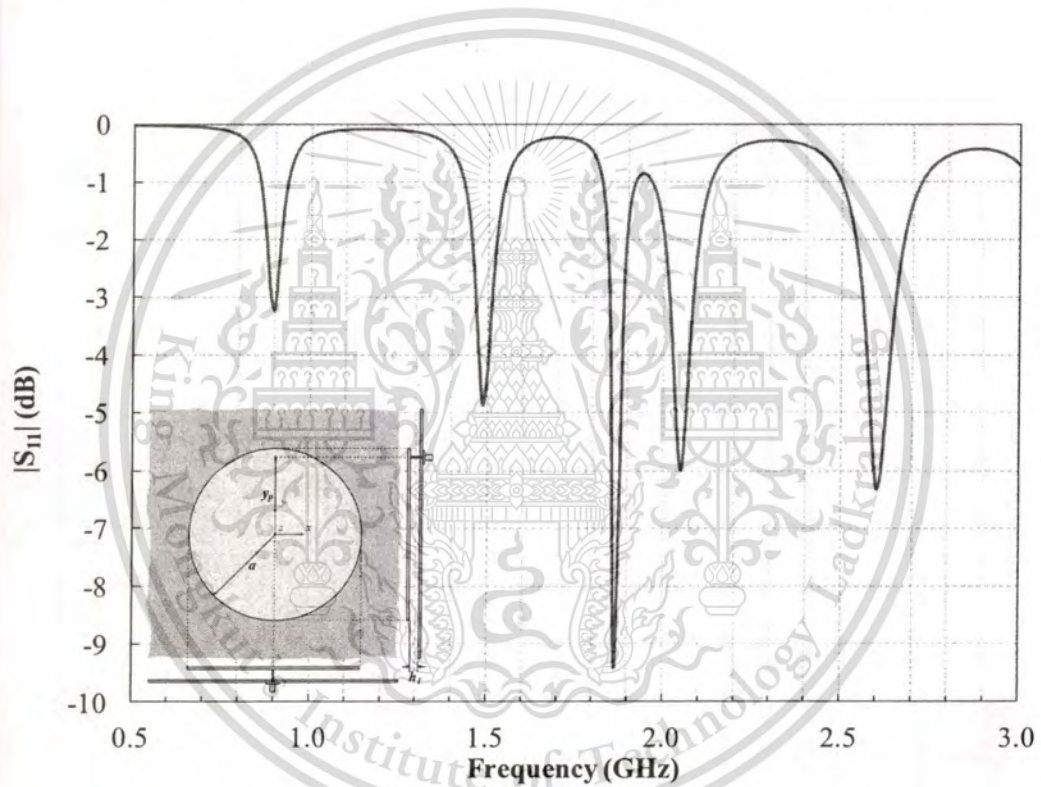

The radius of the radiating circular plate ( $a$ ) can be calculated by using (2.2). Here, the substrate is the air ( $\varepsilon_r = 1$ ) in order to keep away from the dielectric loss. Thus, the parameter  $a$  is equal to 95.3 mm that is used to initial the parameter for simulation. Please keep in mind that based on the cavity model conditions the circular plate antenna has infinite ground plane dimension (the parameters  $g_x$  and  $g_y$  are determined to infinite layer in CST Microwave Studio program). Moreover, this antenna has the spacing between the radiating plate and the ground plane ( $h_l$ ) that is significantly smaller than the wavelength ( $h_l \ll \lambda$ ) at the desired frequencies of operation. The preliminary spacing between the radiating plate and the ground plane is determined to 1.6 mm. The feeding location ( $y_p$ ) of the circular plate antenna is important for the radiation pattern. It is well known that in order to obtain the dominant mode ( $TM_{110}^z$ ), it is closely placed the edge of the radiating circular plate. The initial parameters of the circular plate antenna are tabulated in Table 2.1

**Table 2.1** The initial parameters of the circular plate antenna

Parameter	Dimension (mm)
Radius of annular plate ( $a$ )	95.3
Spacing between annular plate and ground plane ( $h_l$ )	1.6
Dimension of ground plane ( $g_x, g_y$ )	$\infty$
Location of feeding in y-axis ( $y_p$ )	90

From the initial antenna parameters in Table 2.1, it is evident that the circular plate antenna has impedance mismatch at center of lower band frequency ( $f_L=922.5$  MHz) as shown in Fig. 2.3. Therefore, the parameter analysis is performed to find out the

optimum parameters on magnitude of  $S_{11}$ . The parameters of the feeding location along  $y$ -axis ( $y_p$ ), the spacing between the circular plate and the ground plane ( $h_l$ ) and the radius of the circular plate ( $a$ ) are studied. As can be seen in Fig. 2.4, it is found that the feeding location along  $y$ -axis is expected to significant affect on the impedance matching. However, the magnitude of  $S_{11}$  is lower than -10 dB at the 922.5 MHz where the spacing between the radiating circular plate and ground plane ( $h_l$ ) of 1.6 mm. However, the magnitude of  $S_{11}$  better than -10 dB is obtained where  $h_l$  is adjusted as shown in Fig. 2.5. The optimum parameters of circular plate antenna are  $y_p$  of 30 mm and  $h_l$  of 3.2 mm.

**Figure 2.3** Frequency response of the magnitude of  $S_{11}$ , when parameters are in Table 2.1

**Figure 2.4** Frequency response of the magnitude of  $S_{11}$  for various parameter  $y_p$ , when remained parameters are in Table 2.1

**Figure 2.5** Frequency response of the magnitude of  $S_{11}$  for various parameter  $h_1$ , when  $y_p=30$  mm and remained parameters are in Table 2.1

In addition, the parameter  $a$  is adjusted to be 85.3 mm, 90.3 mm and 95.3 mm as shown in Fig. 2.6. It is found that the circular plate antenna can be operated at the frequency of 922.5 MHz when parameter  $a$  is 90.3 mm. The optimum parameters of the antenna are tabulated in Table 2.2. Note that the parameters in table 2.2 are used as the initial parameters of the annular plate antenna that will be discussed in detail in the next section.

**Figure 2.6** Frequency response of the magnitude of  $S_{11}$  for various parameter  $a$ , when  $h_1=3.2$  mm,  $y_p=30$  mm and remained parameters are in Table 2.1

**Table 2.2** The optimum parameters of the circular plate antenna

Parameter	Dimension (mm)
Radius of annular plate ( $a$ )	90.3
Spacing between annular plate and ground plane ( $h_1$ )	3.2
Dimension of ground plane ( $g_x, g_y$ )	$\infty$
Location of feeding in y-axis ( $y_p$ )	30

### 2.3.2 Annular Plate Antenna

From literature review [29]-[31], the annular microstrip antenna has been found that a significant wider bandwidth compared to the other printed circuit resonant antenna. Furthermore, their sizes are substantially smaller than those of corresponding disk antenna with the same operating frequency. A smaller concentric circular slot is proposed to be cut on the original larger circular plate to form an annular-ring antenna as shown in Fig. 2.7. The initial parameters of the annular plate antenna are tabulated in Table 2.3.

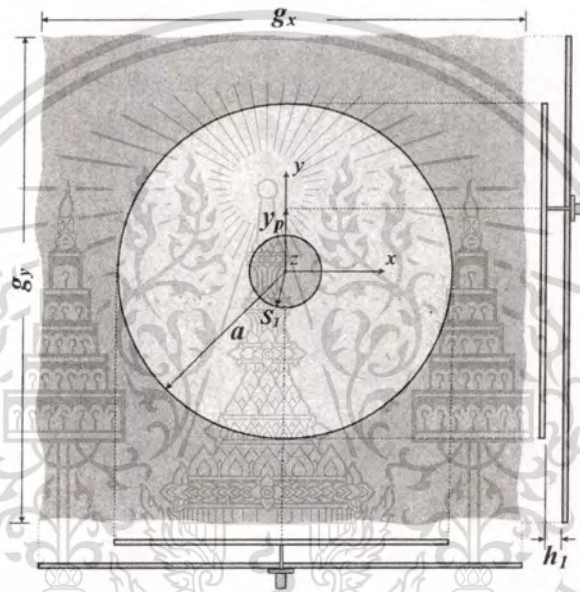

Figure 2.7 An annular plate antenna

Table 2.3 The initial parameters of the annular plate antenna

Parameter	Dimension (mm)
Radius of annular plate ( $a$ )	90.3
Spacing between annular plate and ground plane ( $h_1$ )	3.2
Dimension of ground plane ( $g_x, g_y$ )	$\infty$
Radius of circular slot ( $S_f$ )	10
Location of feeding in y-axis ( $y_p$ )	30

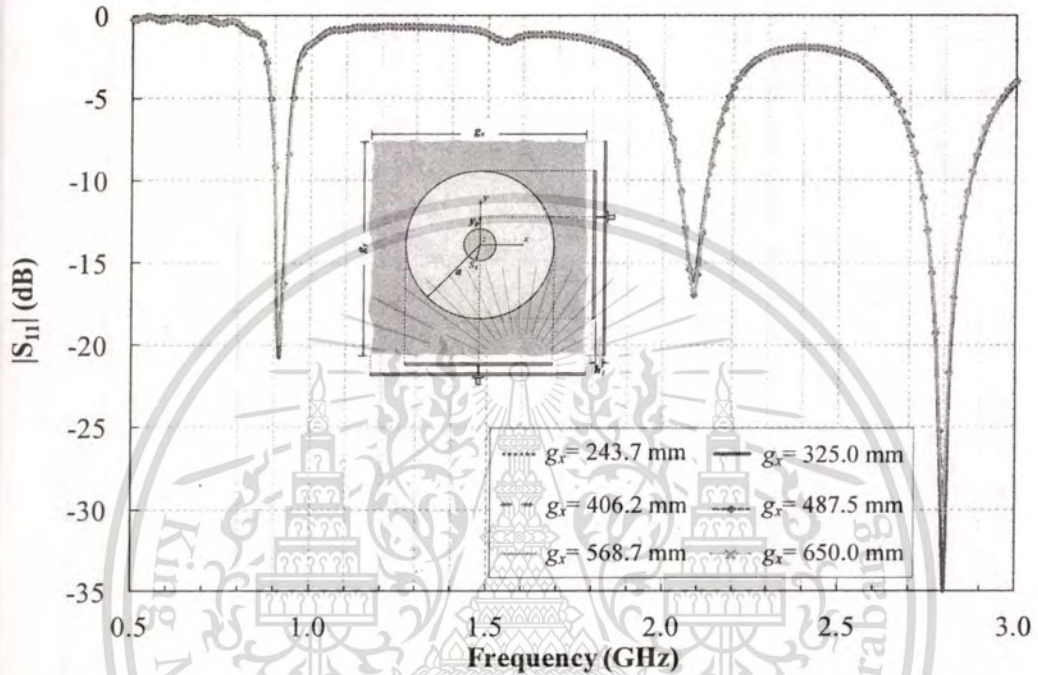

**Figure 2.8** Frequency response of the magnitude of  $S_{11}$  for various parameter  $S_1$ , when remained parameters are in Table 2.3

The radius of a circular slot ( $S_1$ ) affects to the resonant frequency of the annular plate antenna since the electrical size of the annular plate antenna is longer than the conventional circular plate antenna. It is noticed that the resonant frequency is decreased when the radius is increasing as illustrated in Fig. 2.8. To miniaturize the antenna, the parameter  $S_1$  of 15 mm is selected that the resonant frequency of the annular plate antenna is lower than the center frequency of 922.5 MHz. Therefore, the parameter  $a$  must be decreased to reduce the overall size of the annular plate antenna.

In practice, however, the antenna must have a finite size. Consequently, the ground plane dimension is varied in term of the wavelength as depicted in Fig. 2.9. It is obvious that the size of ground plane larger than 243.75 mm ( $0.75\lambda$ ) does not affect to the resonant frequency of the annular plate antenna. The parameters  $g_x$  and  $g_y$  are selected to be 243.75 mm to minimize the antenna size.

Thereafter, the annular plate antenna characteristics are simulated and their parameters are optimized by the CST Microwave Studio. The optimum antenna parameters are obtained as tabulated in Table 2.4. It is found that the annular plate antenna can be operated at the resonant frequency of 922.5 MHz.

**Figure 2.9** Frequency response of the magnitude of  $S_{11}$  for various parameter  $g_x$  and  $g_y$ , when  $S_I=15$  mm and remained parameters are in Table 2.3

**Table 2.4** The optimum parameters of the annular plate antenna

Parameter	Dimension (mm)
Radius of annular plate ( $a$ )	85.3
Spacing between annular plate and ground plane ( $h_I$ )	8
Dimension of ground plane ( $g_x, g_y$ )	217
Radius of circular slot ( $S_I$ )	15
Location of feeding in y-axis ( $y_p$ )	25

Furthermore, in order to achieve the dual-band frequency with unidirectional beam and high-gain antenna, thus the annular plate antenna with curved and rectangular slots is proposed.

### 2.3.3 Annular plate antenna with curved and rectangular slots

The design of antenna to meet a dual-band for UHF and microwave frequencies is studied. To obtain the dual-band characteristics, the annular plate antenna is modified by cutting on the radiating annular plate with curved and rectangular slots. Figure 2.10 shows the surface current on the radiating plate at the frequency of 922.5 MHz. It is found that the surface current intensity is dense at the outer and inner radius areas. Thereby, the curved and rectangular slots are cut on the radiating annular plate at the areas as depicted in Fig. 2.10. Besides, the radiation pattern is desired to a symmetrical unidirectional beam. For this reason, the curved and rectangular slots are symmetrical etched be along y-axis as illustrated in Fig. 2.11.

This section will be focused on the effect of various parameters on the antenna characteristics in microwave band. Therefore, the parameters under consideration focused on their dimensions and locations of the curved slots ( $r_1$ ,  $s_s$ ,  $\phi_1$  and  $\phi_2$ ) and the rectangular slots ( $L_s$ ,  $W_s$ ,  $x_1$  and  $y_1$ ) are varied. The antenna is designed and analyzed to obtain the optimal parameters according to the following procedure.

#### (1) Varying the radius of curved slot ( $r_1$ )

The initial parameters are determined in Table 2.5. Note that the width of curved slot ( $s_s$ ) is  $\lambda_{2.45GHz} / 10$ . Figure 2.12 exhibits the frequency response of the magnitude of  $S_{11}$  for various parameter  $r_1$ , when remained parameters are in Table 2.5. It is obvious that the radius of curved slot ( $r_1$ ) significantly affects only to resonant frequency in microwave band. The optimum parameter  $r_1$  is 77 mm.

Figure 2.10 Surface current at frequency of 922.5 MHz

Figure 2.11 An annular plate antenna with curved and rectangular slots

**Table 2.5** The initial parameters of the annular plate antenna with curved and rectangular slots.

Parameter	Dimension (mm)
Radius of annular plate ( $a$ )	83.5
Spacing between annular plate and ground plane ( $h_1$ )	7.5
Width of ground plane ( $g_x$ )	217
Length of ground plane ( $g_y$ )	217
Length of rectangular slot ( $L_s$ )	61
Radius of curved slot ( $r_l$ )	75
Radius of circular slot ( $S_l$ )	15
Width of curved slot ( $s_s$ )	10
Width of rectangular slot ( $W_s$ )	2
Spacing between rectangular slot and y-axis ( $x_l$ )	17
Spacing between the center of rectangular slot and x-axis ( $y_l$ )	0
Location of feeding in y-axis ( $y_p$ )	25
Length of curved slot ( $\phi_1$ )	120°
Angle between the center of curved slot and y-axis ( $\phi_2$ )	90°

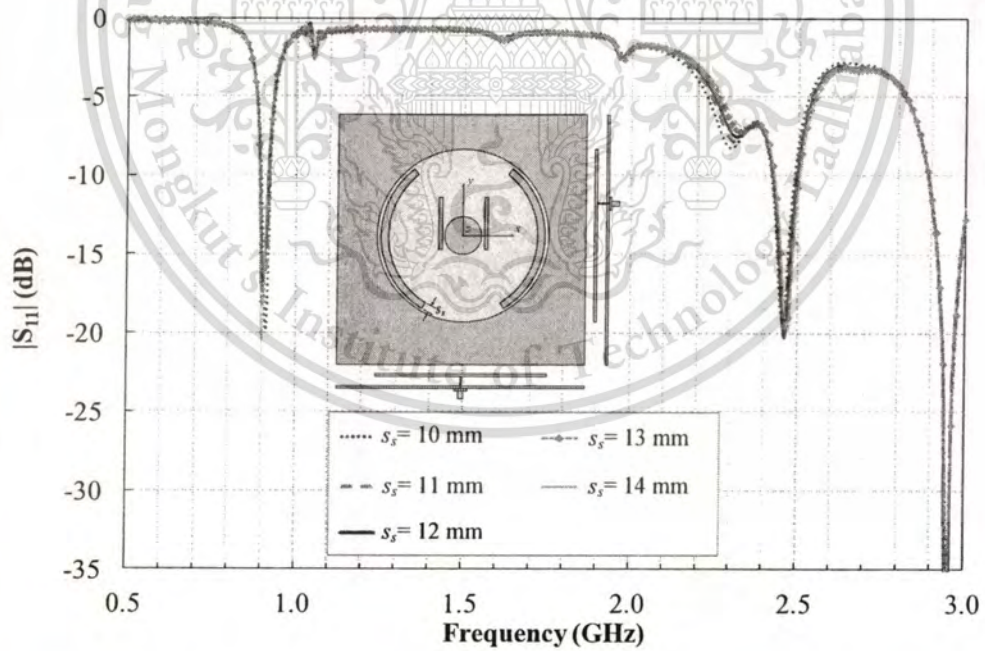

**Figure 2.12** Frequency response of the magnitude of  $S_{11}$  for various parameter  $r_1$ , when remained parameters are in Table 2.5

(2) Varying the length of curved slot ( $\phi_l$ ) and the width of curved slot ( $s_s$ )

The next considering parameter is the length of the curved slots ( $\phi_l$ ). The resonant frequency in microwave band is lower when  $\phi_l$  is increased as illustrated in Fig. 2.13. Note that  $\phi_l$  has no important effect to the resonant frequency at the UHF band. The proper length of the curved slots is 90 mm. After that the width of curved slot ( $s_s$ ) is varied to be 10 mm, 11 mm, 12 mm, 13 mm and 14 mm, which is about  $\lambda_{2.45GHz} / 10$  as illustrated in Fig. 2.14. It is evident that the parameter  $s_s$  does not significantly affect to both bands (UHF and microwave bands). The optimum width of curved slot ( $s_s$ ) is 12 mm. However, the annular plate antenna cannot operate across the microwave band.

**Figure 2.13** Frequency response of the magnitude of  $S_{11}$  for various parameter  $\phi_1$ , when  $r_1=77$  mm and remained parameters are in Table 2.5

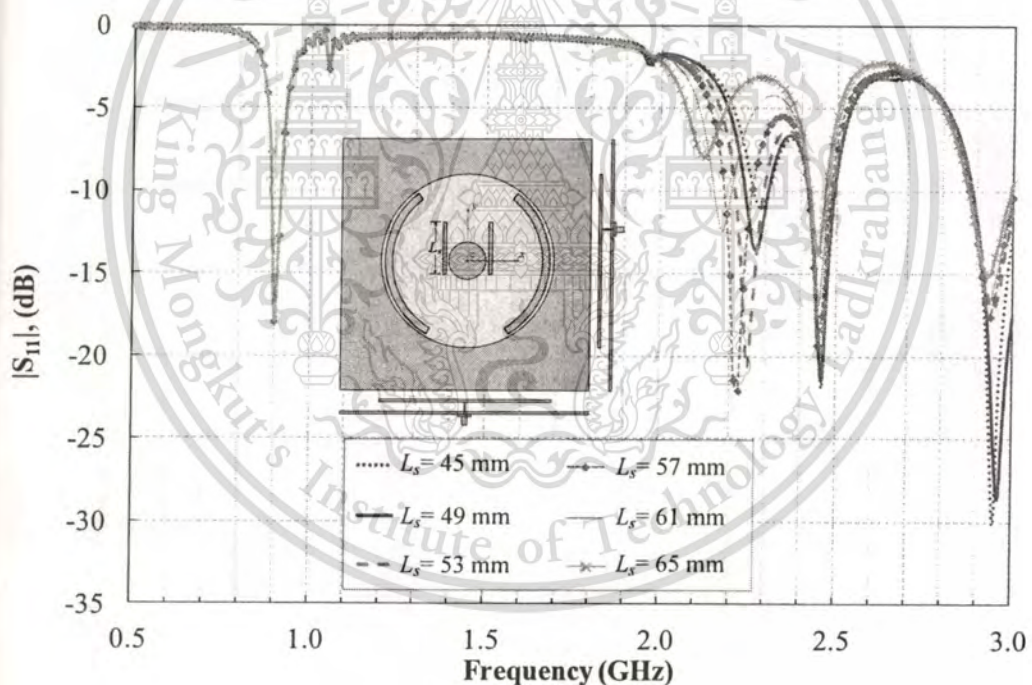

**Figure 2.14** Frequency response of the magnitude of  $S_{11}$  for various parameter  $s_s$ , when  $r_1=77$  mm,  $\phi_1=90$  mm and remained parameters are in Table 2.5

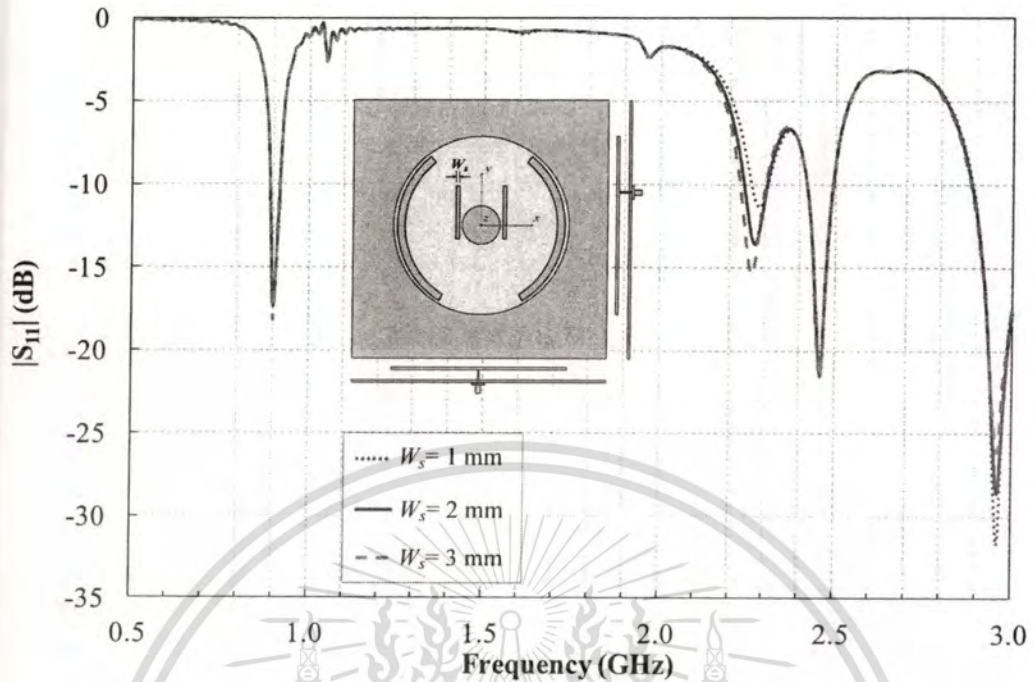

(3) Varying the length of rectangular slot ( $L_s$ ) and the width of rectangular slot ( $W_s$ ) to cover the microwave band

To obtain the magnitude of  $S_{11}$  better than -10 dB across the microwave band, the length and width of rectangular slot are adjusted as shown in Fig. 2.15. In the microwave band, the length of the rectangular slots ( $L_s$ ) has important effect on the antenna bandwidth as illustrated in Fig. 2.15. The length of the rectangular slot ( $L_s$ ) from 45 mm to 65 mm was varied. When the length is shorter, it tends that the antenna has the broader frequency response. The suitable length of rectangular slot ( $L_s$ ) is 49 mm.

Besides the width of rectangular slot ( $W_s$ ) is also adjusted as 1 mm, 2 mm and 3mm. It has slight effects on the level of magnitude of  $S_{11}$  as displayed in Fig. 2.16. Thus, the width of rectangular slot ( $W_s$ ) using the initial parameter is equal to 2 mm.

**Figure 2.15** Frequency response of the magnitude of  $S_{11}$  for various parameter  $L_s$ , when  $r_f=77$  mm,  $\phi_f=90$  mm,  $s_s=12$  mm and remained parameters are in Table 2.5

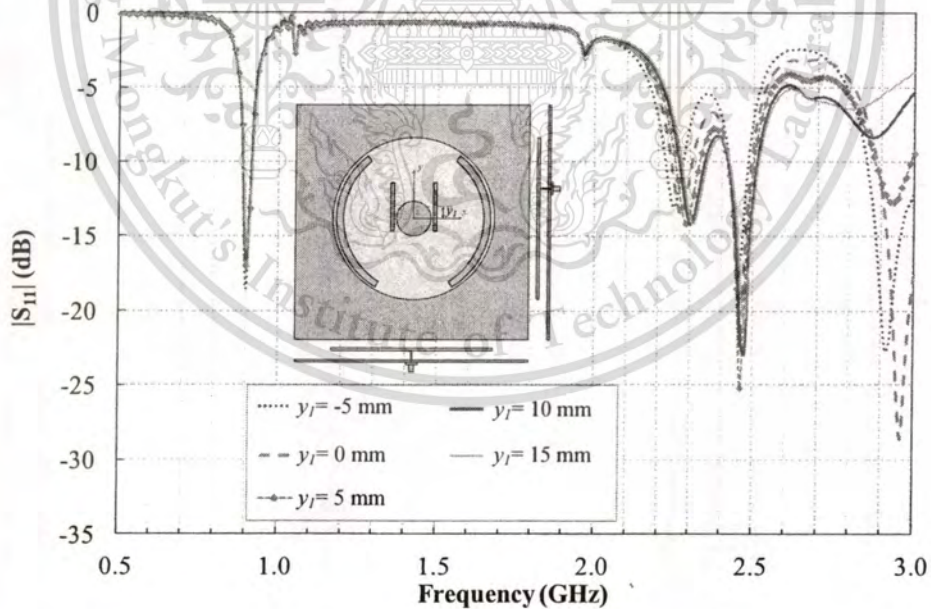

**Figure 2.16** Frequency response of the magnitude of  $S_{11}$  for various parameter  $W_s$ , when  $r_1=77$  mm,  $\phi_1=90$  mm,  $s_s=12$  mm,  $L_s=49$  mm and remained parameters are in Table 2.5

(4) Varying the spacing between rectangular slot and y-axis ( $x_1$ ) and spacing between the center of rectangular slot and x-axis ( $y_1$ )

Figure 2.17 and Figure 2.18 show the effect of the spacing between rectangular slot and y-axis ( $x_1$ ) and spacing between the center of rectangular slot and x-axis ( $y_1$ ) on the magnitude of  $S_{11}$ . It is obvious that parameters  $x_1$  and  $y_1$  affect to the antenna bandwidth in microwave band. The appropriate parameters of the spacing between rectangular slot and y-axis ( $x_1$ ) and spacing between the center of rectangular slot and x-axis ( $y_1$ ) are 17 mm and 10 mm, respectively. Accordingly, the optimum parameters of the annular plate antenna with curved and rectangular slots are tabulated in Table 2.6.

**Figure 2.17** Frequency response of the magnitude of  $S_{11}$  for various parameter  $x_I$ , when  $r_I=77$  mm,  $\phi_I=90$  mm,  $s_s=12$  mm,  $L_s=49$  mm,  $W_s=2$  mm and remained parameters are in Table 2.5

**Figure 2.18** Frequency response of the magnitude of  $S_{11}$  for various parameter  $y_I$ , when  $r_I=77$  mm,  $\phi_I=90$  mm,  $s_s=12$  mm,  $L_s=49$  mm,  $W_s=2$  mm,  $x_I=17$  mm and remained parameters are in Table 2.5

**Table 2.6** The optimum parameters of the annular plate antenna with curved and rectangular slots

Parameter	Dimension (mm)
Radius of annular plate ( $a$ )	83.5
Spacing between annular plate and ground plane ( $h_1$ )	7.5
Width of ground plane ( $g_x$ )	217
Length of ground plane ( $g_y$ )	217
Length of rectangular slot ( $L_s$ )	49
Radius of curved slot ( $r_1$ )	77
Radius of circular slot ( $S_1$ )	15

Width of rectangular slot ( $W_s$ )	2
Spacing between rectangular slot and y-axis ( $x_1$ )	17
Spacing between the center of rectangular slot and x-axis ( $y_1$ )	10
Location of feeding in y-axis ( $y_p$ )	25
Length of curved slot ( $\phi_1$ )	90°
Angle between the center of curved slot and y-axis ( $\phi_2$ )	90°

From the simulated results of the annular plate antenna with curved and rectangular slots on vertical ground plane with the optimum parameters in Table 2.6, the magnitude of  $S_{11}$  is shown in Fig. 2.19. At the center frequency of UHF band of 922.5 MHz, the radiation pattern is a unidirectional beam as illustrated in Fig. 2.20. However, the radiation pattern at frequency of 2.45 GHz is a unidirectional with a tilt angle as shown in Fig. 2.21. Thus, the modified antenna is performed to improve the radiation pattern in microwave band that the vertical ground plane is used, which will be discussed in detail in the next section.

### 2.3.4 An annular plate antenna with curved and rectangular slots on vertical ground plane

From the previous section, in microwave band, the annular plate antenna with curved and rectangular slots has the unidirectional pattern with beam tilt-angle. Several techniques can be used for improvement. In this study, a modified ground plane technique is utilized that can compensate for the beam tilt angles. The vertical ground plane is applied as shown in Fig. 2.22. The initial parameters of the annular plate antenna with curved and rectangular slots on vertical ground plane are illustrated in Table 2.7.

Figure 2.23 and Figure 2.24 present frequency responses of the magnitude of  $S_{11}$  and radiation patterns at frequency of 922.5 MHz and 2.45 GHz for various heights of vertical ground plane ( $h_2$  and  $h_3$ ), when parameters are in Table 2.7. It is obvious that  $h_2$  and  $h_3$  has important effect to the level of magnitude of  $S_{11}$ . Furthermore, the height of

vertical ground plane can improve the radiation pattern in microwave band. The selected  $h_2$  and  $h_3$  are 40 mm and 45 mm, respectively.

This section presents the annular plate antenna with curved and rectangular slots on vertical ground plane to operate the dual-band frequency of UHF and microwave band. The optimum parameters are summarized in Table 2.8. Note that the radiation pattern in microwave band trends to be a unidirectional beam in broadside direction that it will be optimized using the optimization function in CST Microwave Studio to achieve a unidirectional pattern.

## 2.4 Antenna Optimization

This section presents the characteristics of the annular plate antenna with curved and rectangular slots on vertical ground plane using the optimization function in the CST Microwave Studio. The initial parameters for the optimization function are tabulated in Table 2.8. Subsequently, the optimum parameters are shown in Table 2.9 with the simulated results.

**Table 2.9** The parameters of the annular plate antenna with curved and rectangular slots on vertical ground plane using the optimization function in the CST Microwave Studio.

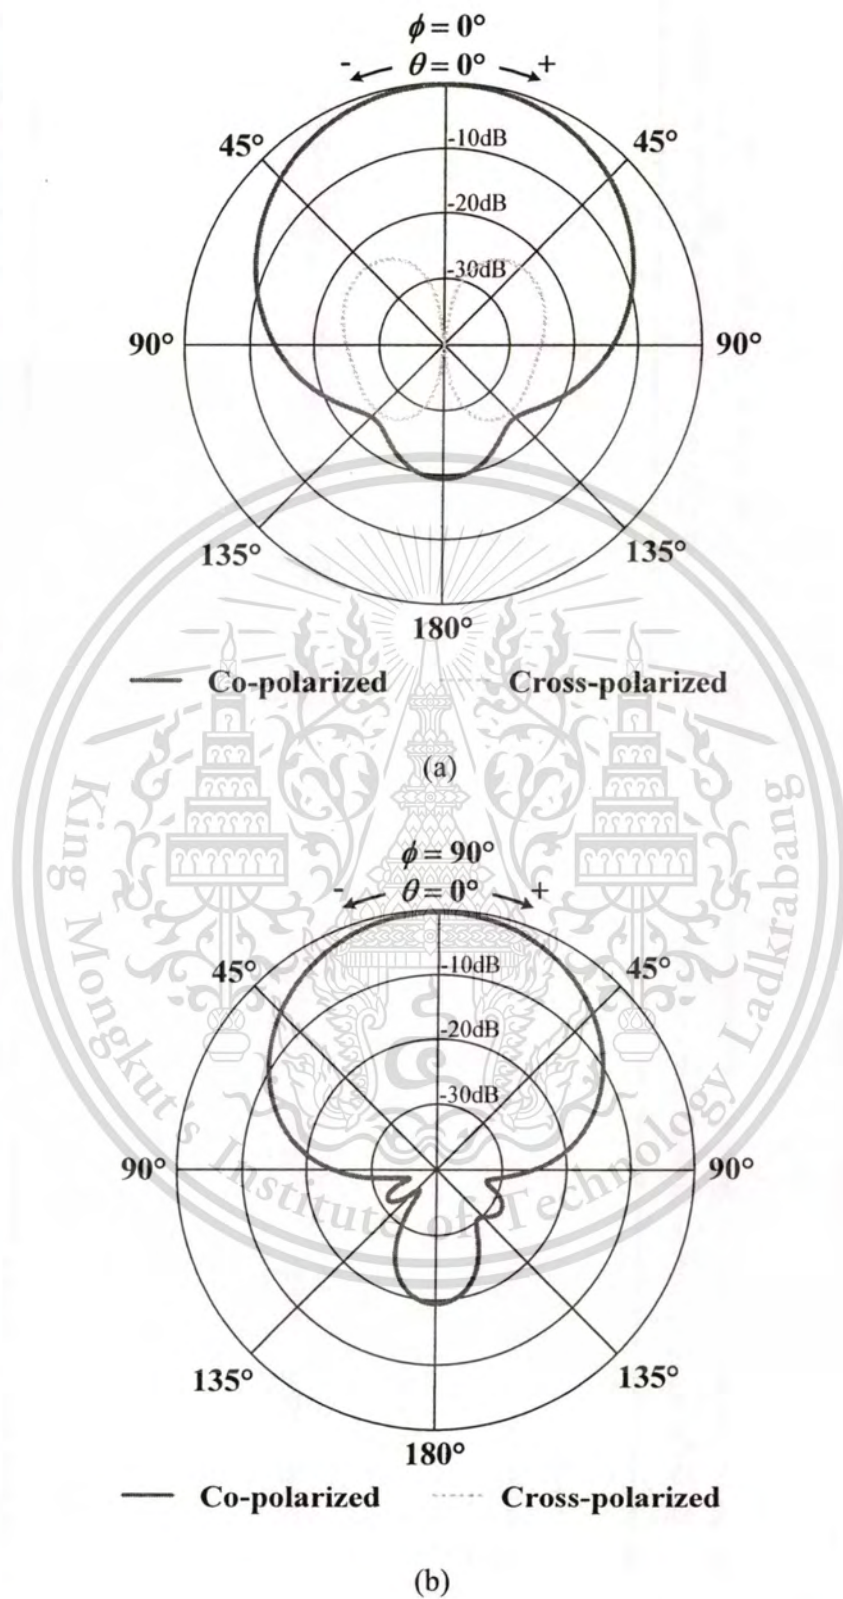

Parameter	Dimension (mm)
Radius of annular plate ( $a$ )	83.5
Spacing between annular plate and ground plane ( $h_1$ )	7.5
Height of vertical ground plane in x-axis ( $h_2$ )	40
Height of vertical ground plane in y-axis ( $h_3$ )	50
Width of ground plane ( $g_x$ )	187.5
Length of ground plane ( $g_y$ )	225.5
Length of rectangular slot ( $L_s$ )	49.5
Radius of curved slot ( $r_1$ )	72.5
Radius of circular slot ( $S_1$ )	18
Width of curved slot ( $s_s$ )	11.5
Width of rectangular slot ( $W_s$ )	2
Spacing between rectangular slot and y-axis ( $x_1$ )	25
Spacing between the center of rectangular slot and x-axis ( $y_1$ )	14.5
Location of feeding in y-axis ( $y_p$ )	26
Length of curved slot ( $\phi_1$ )	100°
Angle between the center of curved slot and y-axis ( $\phi_2$ )	90°

The annular plate antenna with curved and rectangular slots on vertical ground plane can be operated a dual-band from 912 MHz to 925 MHz (13 MHz) and from 2.32 GHz to 2.69 GHz (360 MHz) as shown in Fig. 2.25.

**Figure 2.25** Frequency response of the magnitude of  $S_{11}$  when remained parameters are in Table 2.9

The radiation patterns are unidirectional beam for both frequencies of UHF and microwave bands. Figures 2.26, 2.27 and 2.28 show the radiation patterns at frequencies of 920 MHz, 922.5 MHz and 925 MHz, respectively. Let us consider at the center frequency the UHF band (922.5 MHz), the half-power beamwidths in  $xz$ -plane and  $yz$ -plane are  $50^\circ$  and  $80^\circ$ , respectively. The radiation patterns at frequencies of 2.40 GHz, 2.45 GHz and 2.50 GHz are illustrated in Fig. 2.29, 2.30 and 2.31, respectively. At the center frequency of microwave band (2.45 GHz), the half-power beamwidths in  $xz$ - and  $yz$ -planes are  $35^\circ$  and  $10^\circ$ , respectively.

**Figure 2.26** Radiation pattern at the frequency of 920 MHz (a) xz-plane (b) yz-plane

**Figure 2.27** Radiation pattern at the frequency of 922.5 MHz (a) xz-plane (b) yz-plane

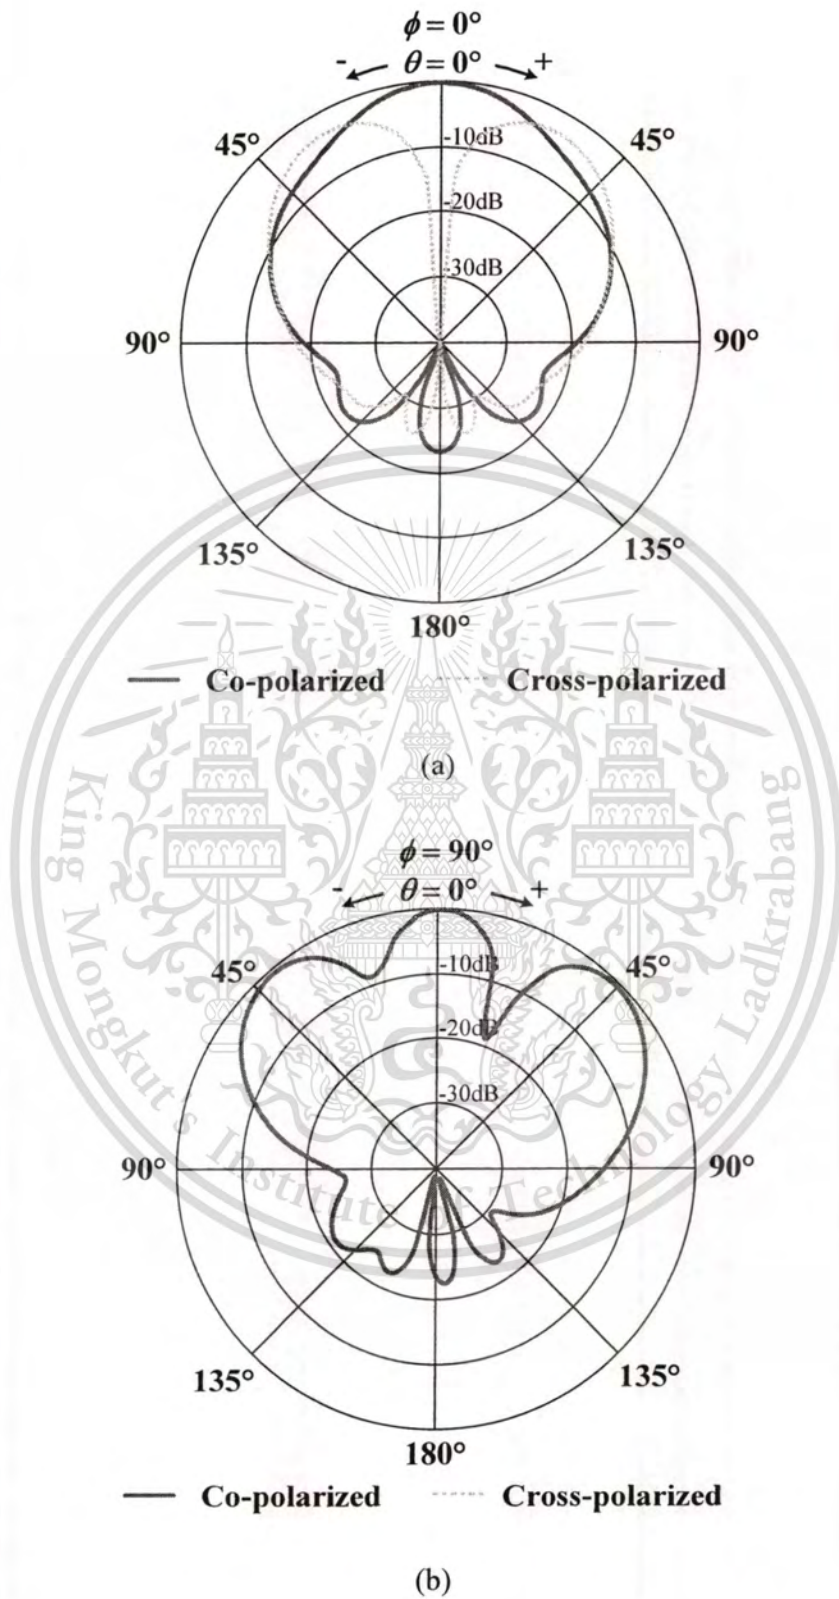

**Figure 2.28** Radiation pattern at the frequency of 925 MHz (a) xz-plane (b) yz-plane

**Figure 2.29** Radiation pattern at the frequency of 2.40 GHz (a) xz-plane (b) yz-plane

**Figure 2.30** Radiation pattern at the frequency of 2.45 GHz (a) xz-plane (b) yz-plane

**Figure 2.31** Radiation pattern at the frequency of 2.50 GHz (a) xz-plane (b) yz-plane

Considering the frequency ranges from 920 MHz to 925 MHz and from 2.4 GHz to 2.5 GHz, the antenna gain is depicted in Fig. 2.32. It is found that the antenna gains at frequencies of 922.5 MHz and 2.45 GHz are 8.3 dBi and 10.4 dBi, respectively. Besides the radiation efficiencies in UHF band are about 97 % and more than 99 % in microwave band as exhibited in Fig. 2.33.

**Figure 2.32** Antenna gain (a) UHF band (b) microwave band

(a)

(b)

**Figure 2.33** The radiation efficiency (a) UHF band (b) microwave band

Considering the surface current on the radiating annular plate with the curved and rectangular slots, it is evident that the surface current in UHF band is dense at the outer and inner radii of annular plate as shown in Fig. 2.34. For microwave band, the surface current is intense at the curved and rectangular slots as shown in Fig. 2.35. From the results, it is implied that the annular plate is considerable component to respond in UHF band and the curved and rectangular slots are considerable components to respond in microwave band.

## 2.5 Summary

This chapter discussed the design and simulation to determine the optimum parameters of the annular plate antenna with curved and rectangular slots on vertical ground plane. The proposed antenna is employed to the RFID reader antenna that it can be operated in a dual-band of UHF and microwave band. Using the slot techniques, the antenna can be responded at the dual frequency band. To obtain the high-gain and avoid the dielectric loss in lossy material substrate that air is used as antenna substrate. From the simulated results, the magnitude of  $S_{11}$  of the annular plate antenna with curved and rectangular slots on vertical ground plane better than -10 dB from 912 MHz to 925 MHz (13 MHz) and from 2.32 GHz to 2.69 GHz (360 MHz) that can cover the UHF and microwave bands in RFID application. The radiation patterns are unidirectional beam at both of frequencies. The half-power beamwidths in xz-plane and yz-plane are 80° and 50° at frequency of 922.5 MHz and the half-power beamwidths in xz-plane and yz-plane are 35° and 10° at frequency of 2.45 GHz. In addition, the antenna gains are 8.3 dBi in UHF band and in the range of 9 dBi to 10.4 dBi in microwave band. The radiation efficiencies are about 97 % for UHF band and more than 99 % for microwave band.

## CHAPTER 3

# THE RFID SENSOR DESIGN

### 3.1 Introduction

In this chapter, the RFID background and theory is discussed, and the RFID tag design is presented by using the electromagnetic simulator to obtain the maximum tag performance. These RFID tags are applied as remotely read dielectric-property sensors, called a novel RFID sensor, to determine qualities of some material of interest. In addition, the relation between the dielectric constant and maximum read range of the RFID reader and RFID tag are illustrated. Finally, the sensitivity analysis of the RFID tag is also mentioned in this chapter.

### 3.2 Background and Theory

The demand for traceability to identify and inspect qualities of material products through nondestructive testing (NDT) techniques has been on the rise. Several NDT techniques, such as Radar, Capacimetry, Electrical Resistance and Ultrasonic waves, have been extensively used. Each technique however has its advantages and disadvantages, so the selection of an appropriate technique is based on the desired application. For such construction materials (CMs) as Light Weight Concrete (LWC), Mortar specimens and Concrete, a reliable NDT technique is required to evaluate their properties whether they are suitable for construction use. Therefore, the development of a reliable sensor technique to determine material quality in manufacturing and/ or material testing and inspection process is necessary.

For the ultra high frequency (UHF) and microwave frequency identification systems [32], passive modulated backscatter RF tags communicate with a reader, using far-field electromagnetic (EM) waves, and these tags typically modulate the EM waves

scattered from tag antennas using the load modulation [32]. To maximize the tag performance, tag antennas must be appropriately designed to conjugately match the chip impedance [33].

One important factor of tag performance is the read range of the passive RFID system, defined as the maximum distance from which a tag can be detected. One limitation on the read range is the maximum distance from which the tag receives merely sufficient power to turn on and scatter back. Another limitation is the maximum distance from which the reader can detect this scattered signal. The read range is the smaller of the two maximum distances. Typically, the former determines the read range since the RFID reader sensitivity is usually high [34]. From the sensor's viewpoint, the dependency of the read range on EM properties of CMs near or in contact with tags can be employed as an approach to determining quality of CMs through their estimated dielectric constants. Note that the RF tag performance is affected by many factors, including EM properties of objects near or in contact with tags.

In this chapter, an NDT technique, called a novel RFID sensor, operating in the UHF band of 922.5 MHz is proposed to determine quality of certain CMs through their estimated dielectric properties. Generally, the traditional RFID sensors require additional specific sensors, such as humidity, temperature, motion, light and sound sensors, to be integrated with RFID tags. On the other hand, the novel RFID sensor does not require additional specific sensors to determine dielectric properties of the materials under test, thereby more convenient in fabrication and usually of lower cost. In addition, the novel RFID sensor does not require a network analyzer and other expensive accessories. The key component of the novel RFID sensor is the tag specifically designed to achieve the conjugate impedance matching condition between the tag antenna and a chip in the presence of a selected member of the family of materials of interest, which is near or in contact with the tag. Typically, two specifically designed tags (SDTs), to subsequently discuss in greater detail, for selected members of the family are required to uniquely determine the dielectric properties of a lossy CM of interest.

**Figure 3.1** A novel RFID sensor system

Figure 3.1 illustrates a novel RFID sensor system consisting of the RFID reader, the reader antenna and SDTs, where each SDT is placed near or in contact with a material under test. Note that the read range is normally governed by the maximum distance from which a tag receives just sufficient power to turn on and scatter back due to the fact that the RFID reader sensitivity is usually high. Generally, the maximum distance can be calculated by using Friis transmission equation [35] that it can be written as

$$R_{\max,mat} = \frac{\lambda}{4\pi} \sqrt{\frac{P_{\text{reader-tx}} \cdot G_{\text{reader-tx}} \cdot \tau_{\text{reader-tx}} \cdot \tau_{\text{tag}} \cdot G_{\text{tag,fs}}}{L_{\text{sys}} \cdot P_{\text{tag,th}}}}, \quad (3.1)$$

where  $P_{\text{reader-tx}}$  is the input power to the reader antenna,  $L_{\text{sys}}$  is the system loss in both tag and reader,  $G_{\text{reader-tx}}$  is the gain of the reader antenna,  $P_{\text{tag,th}}$  is the minimum threshold power necessary to power up the chip,  $G_{\text{tag,fs}}$  is the tag antenna gain in free space,  $\lambda$  is the free space wavelength,  $\tau_{\text{reader-tx}}$  and  $\tau_{\text{tag}}$  are the power transmission coefficients of the reader antenna and tag, respectively. Refer to [36], [37] using the modified Friis transmission equation, the maximum distance ( $R_{\max,mat}$ ) of tags in the presence of material products near or in contact with tags can be calculated, under the assumption that the reader antenna has perfect impedance matching and perfect polarization matching to the tag antenna. In addition, Griffin et al. proposed new forms of the power and backscatter communication radio link budgets in terms of the gain penalty based on the modified Friis transmission equation, which is the decrease in tag antenna gain from its free space value when attached to a material, and these forms allow RF tag designers to quantify the effects of tag material attachment [38], [39], as follows:

$$R_{\max,mat} = \frac{\lambda}{4\pi} \sqrt{\frac{P_{reader-tx} \cdot G_{reader-tx} \cdot \tau_{mat} \cdot \left(\frac{G_{tag,fs}}{GP}\right)}{L_{sys} \cdot P_{tag,th}}}, \quad (3.2)$$

Note that the gain penalty  $GP$  due to the presence of a material product is mathematically defined as

$$GP \equiv \frac{G_{tag,fs}}{G_{tag,mat}} \quad (3.3)$$

where  $\tau_{mat}$  is the power transmission coefficient in the presence of a material product. In general, the power transmission coefficient  $\tau$  can be expressed in terms of the power-wave reflection coefficient  $\Gamma_p$  at the tag antenna terminal as [33], [40]

$$\tau = 1 - |\Gamma_p|^2, \quad (3.4)$$

where

$$\Gamma_p \equiv \frac{Z_{chip} - Z_{ant,tag}^*}{Z_{chip} + Z_{ant,tag}} \quad (3.5)$$

In (3.5), the superscript “\*” denotes the complex conjugate symbol, and  $Z_{chip}$  and  $Z_{ant,tag}$  are the chip impedance and the tag antenna impedance, respectively. Note that when the chip impedance and the tag antenna impedance are conjugately matched ( $Z_{chip} = Z_{ant,tag}^*$ ),  $\Gamma_p$  is equal to zero and  $\tau$  is equal to one as expected.

Similarly, the maximum distance ( $R_{\max,fs}$ ) of tags in free space can be calculated under the same assumption as  $R_{\max,mat}$  as follows:

$$R_{\max,fs} = \frac{\lambda}{4\pi} \sqrt{\frac{P_{reader-tx} \cdot G_{reader-tx} \cdot \tau_{fs} \cdot G_{tag,fs}}{L_{sys} \cdot P_{tag,th}}} \quad (3.6)$$

where  $\tau_{fs}$  is the power transmission coefficient associated with the tag antenna in free space. It should be pointed out that the term  $GP$  in (3.6) is equal to 1 since tags are in the free space. From (3.2) and (3.6), the ratio of  $R_{\max,mat}$  to  $R_{\max,fs}$  can be expressed compactly as

$$\frac{R_{\max,mat}}{R_{\max,fs}} = \sqrt{\frac{\tau_{mat}}{\tau_{fs}} \left( \frac{1}{GP} \right)} \quad (3.7)$$

where all common terms in (3.2) and (3.6) are cancelled out and only terms associated with the power transmission coefficients and the tag antenna gains remain. In (3.7), only terms  $\tau_{mat}$  and  $GP$  are dependent on properties of material products near or in contact with tags; e.g., their dielectric constants, sizes and shapes, in a complicated fashion. Thus, the ratio  $R_{\max,mat}/R_{\max,fs}$  can usually be obtained via measurements or numerical simulations of associated problems. Note that all parameters on the right-hand side of (3.7) are related to two parameters of tag antennas; i.e., the tag antenna impedance and the tag antenna gain, in free space and in the presence of a material product. Once the ratio  $R_{\max,mat}/R_{\max,fs}$  is known, the dielectric constant of the material product of interest can be estimated to determine their qualities using appropriate data processing. The procedure of dielectric constant determination will be illustrated via specific examples in the chapter 5.

### 3.3 RFID Tag Design and Simulation

**Figure 3.2** The novel RFID sensor setup

Figure 3.2 shows the novel RFID sensor setup in an anechoic chamber, where the operating frequency of interest is 922.5 MHz. The proposed RFID sensor employs the UHF RFID reader of Symbol XR450 and the reader antenna using the Anritsu antenna with the model of MP651A as a half-wavelength standard tuned dipole antenna [41]. Owing to the fact that the standard dipole has the linear polarization and tag antennas are designed to achieve the same polarization as the standard dipole, there is no polarization mismatch. In addition, due to the fact that the RFID reader sensitivity is high, the read range is equal to the maximum distance from tag calculated by using the modified Friis transmission equation as shown in (3.2). In this study, all tags are designed via the CST Microwave Studio simulator [42] and using the IC chip NXP UCODE G2XL, where its input impedance is equal to  $16.5 - j148.7 \Omega$  at 922.5 MHz [43]. In Fig. 3.2, the LWC is employed as an example of CMPs to illustrate the concept of the novel RFID sensor. Note that the LWC is assumed to be homogeneous and it can usually be used to construct buildings due to its light weight, easily sawn and sculpted, and nailed or screwed without pre-drilling [44].

Typically, the actual dimension for commercial application of LWC is 20 cm  $\times$  60 cm  $\times$  7.5 cm [45]. Its sample with the dimension of 20 cm  $\times$  15 cm  $\times$  7.5 cm is

considered in this chapter. The following parameters are employed:  $P_{reader-tx} = 20$  dBm,  $L_{sys} = 1.01$  dB,  $G_{reader-tx} = 2.15$  dBi and  $P_{tag,th} = -15$  dBm. All SDTs are fabricated on the 0.8 mm-FR4 substrate with the dielectric constant of 4.3. Two cases are considered; i.e., lossless and lossy LWCs. The former will be considered first since it is simpler to understand the methodology of the proposed RFID sensor, while the latter is more complicated, but more realistic.

For the lossy case, two LWC states are considered; i.e., the dry state and the saturated state with water. In literature, the constitutive parameters of building materials were measured [46]-[50]. Note that the dielectric constant of the lossy case can be measured using the dielectric probe [51]. Table 3.1 illustrates the dielectric constants,  $\epsilon_r$ , of each lossy LWC state, where  $\epsilon_r$  is defined as  $\epsilon_r = \epsilon'_r - j\epsilon''_r$ . As expected,  $\epsilon'_r$  and  $\epsilon''_r$  of the saturated state are larger than  $\epsilon'_r$  and  $\epsilon''_r$  of the dry state respectively, due to the water existing in the saturated state.

**Table 3.1** Dielectric constant of lossy LWCs.

LWC state	$\epsilon'_r$	$\epsilon''_r$
Dry	2.5	0.2
Saturated	8	1.08

To obtain the optimum SDTs, the design process are discussed as follows

### 3.3.1 Lossless Case

For the lossless LWC case, it is assumed that its dielectric constant is equal to the dielectric constant of LWC in the dry state with no loss; i.e.,  $\epsilon_r = \epsilon'_r = 2.5$  and  $\epsilon''_r = 0$ . Using the CST Microwave Studio simulator, the tag antenna of the SDT, called the  $SDT_{LL}$ , is appropriately designed to conjugately match with the chip impedance by including effects of the lossless LWC in the simulation, where the  $SDT_{LL}$  is attached to

the surface of the lossless LWC at its center as shown in Fig. 3.3 to reduce edge effects. Symmetrical meander line antennas are employed in this chapter with an inductively coupled structure with 1-mm line thickness [52] to flexibly meet the high Q-factor of the IC chip NXP UCODE G2XL. In addition, the tag antenna size must be compact to mount on small LWCs as well. The tag antenna structure is optimized as shown in Fig. 3.4, where its antenna parameters are illustrated in Table 3.2.

Figure 3.3 The SDT location on the LWC

Figure 3.4 The SDT for the lossless LWC

**Table 3.2** Parameters of the SDT<sub>LL</sub> for the lossless LWC with  $\epsilon_r = 2.5$ .

Parameter	Dimension (mm)	Parameter	Dimension (mm)
$a_1$	12	$b_4$	23
$a_2$	5	$L$	39.5
$a_3$	17.5	$s_1$	1
$a_4$	5	$s_2$	1.75
$a_5$	38.5	$s_3$	5
$b_1$	16.5	$s_4$	3
$b_2$	1.5	$W$	25
$b_3$	18.5		

Note that the dimensions of the SDT<sub>LL</sub> are equal to 39.5 mm × 25 mm × 0.8 mm after optimization, where its input impedance is equal to  $17.75 + j147.8 \Omega$ , and its polarization in the bore-sight direction looking out from the LWC is horizontal. In addition, its gain and power transmission coefficient ( $G_{tag,mat}$  and  $\tau_{mat}$ ) are found to be -0.49 dBi and 99.8 %, respectively. Note that  $\tau_{mat}$  of the SDT<sub>LL</sub> is almost equal to 100 % illustrating that the input impedances of the SDT<sub>LL</sub> and the IC chip are almost conjugately matched as desired.

To show the dependency of  $G_{tag,mat}$  and  $\tau_{mat}$  on  $\epsilon_r$ , Fig. 3.5 illustrates the plots of  $G_{tag,mat}$  in dBi and  $\tau_{mat}$  in percentage for the SDT<sub>LL</sub> as a function of  $\epsilon_r$  ranging from 2.5 to 8.0. It is found that its  $G_{tag,mat}$  and  $\tau_{mat}$  monotonically decrease as  $\epsilon_r$  increases, where both  $G_{tag,mat}$  and  $\tau_{mat}$  are maximum at  $\epsilon_r = 2.5$ . Due to the fact that the SDT<sub>LL</sub> is specifically designed to conjugately match with the chip impedance in the presence of the

lossless LWC with  $\epsilon_r = 2.5$ , more impedance mismatch occurs as increasing  $\epsilon_r$ , resulting in decreasing  $\tau_{mat}$  as expected.

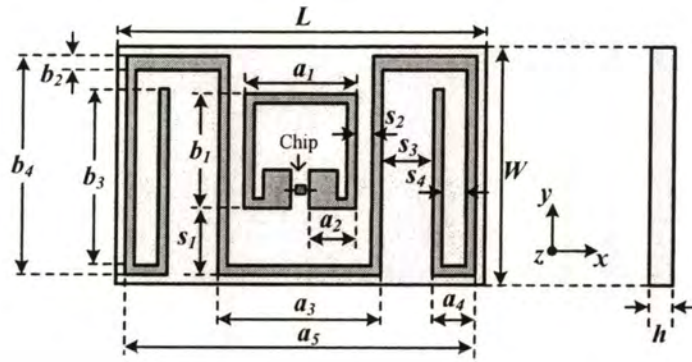

Figure 3.5  $G_{tag,mat}$  and  $\tau_{mat}$  as a function of  $\epsilon_r$  for the SDT<sub>LL</sub>.

### 3.3.2 Lossy Case

For the lossy LWC case, the tags are specifically designed for optimum performance for each state of lossy LWCs as shown in Table 3.1. The RFID tag structures optimized for the dry LWC state, called the SDT<sub>1</sub>, and for the saturated LWC state, called the SDT<sub>2</sub>. They are illustrated in Fig. 3.6(a) and Fig. 3.6(b) respectively, where their parameters are shown in Table 3.3. The dimensions of the SDT<sub>1</sub> and the SDT<sub>2</sub> are equal to 39.5 mm × 25 mm × 0.8 mm and 39 mm × 20.5 mm × 0.8 mm respectively, where their characteristics are tabulated in Table 3.4. It should be pointed out that  $\tau_{mat}$  of both SDT<sub>1</sub> and SDT<sub>2</sub> are nearly equal to 100 % as desired.

(a) Dry LWC SDT ( $SDT_1$ )(b) Saturated LWC SDT ( $SDT_2$ )**Figure 3.6** The SDTs for the lossy LWCs

To illustrate the dependency of  $G_{tag,mat}$  and  $\tau_{mat}$  on  $\epsilon_r'$  for two specific values of  $\epsilon_r''$ , let first consider  $\epsilon_r''=0.2$  as shown in Fig. 3.7, where the  $SDT_1$ , specifically designed for  $\epsilon_r=2.5-j0.2$ , is employed in this study. Like the lossless case, it is found that  $\tau_{mat}$  tends to decrease as  $\epsilon_r'$  increases as expected due to more impedance mismatch. In addition,  $G_{tag,mat}$  varies noticeably as  $\epsilon_r'$  increases. Next, let consider another case of  $\epsilon_r''=1.08$  as shown in Fig. 3.8, where the  $SDT_2$ , specifically designed for  $\epsilon_r=8.0-j1.08$ , is employed.

Figure 3.7  $G_{tag,mat}$  and  $\tau_{mat}$  as a function of  $\epsilon'_r$  for the SDT<sub>1</sub> with  $\epsilon''_r = 0.2$

Figure 3.8  $G_{tag,mat}$  and  $\tau_{mat}$  as a function of  $\epsilon'_r$  for the SDT<sub>2</sub> with  $\epsilon''_r = 1.08$

**Table 3.3** Tag parameters for the lossy LWCs.

Parameter	Dimension (mm)		Parameter	Dimension (mm)	
	$SDT_1$	$SDT_2$		$SDT_1$	$SDT_2$
$a_1$	12	17	$b_4$	23	18.5
$a_2$	5	7.5	$L$	39.5	39
$a_3$	17.5	21	$s_1$	6	3
$a_4$	4.5	3	$s_2$	1.75	1
$a_5$	37.5	37	$s_3$	5.5	5
$b_1$	12	6	$s_4$	2.5	1
$b_2$	1.5	2	$W$	25	20.5
$b_3$	19.5	8			

**Table 3.4** SDT characteristics for the lossy LWCs.

SDT Characteristic	$SDT_1$	$SDT_2$
Input impedance ( $\Omega$ )	$14.09 + j149.41$	$16.09 + j147.64$
$G_{tag,mat}$ (dBi)	-8.66	-10.67
$\tau_{mat}$ (%)	99.33	98.88
Polarization	Linear	Linear

### 3.4 The Relation between Dielectric Constant and Maximum Read Range ( $R_{\max}$ )

This section presents the relation between dielectric constant and maximum read range ( $R_{\max}$ ), which it is used to determine material quality in manufacturing and/ or material testing and inspection process.

#### 3.4.1 Lossless Case

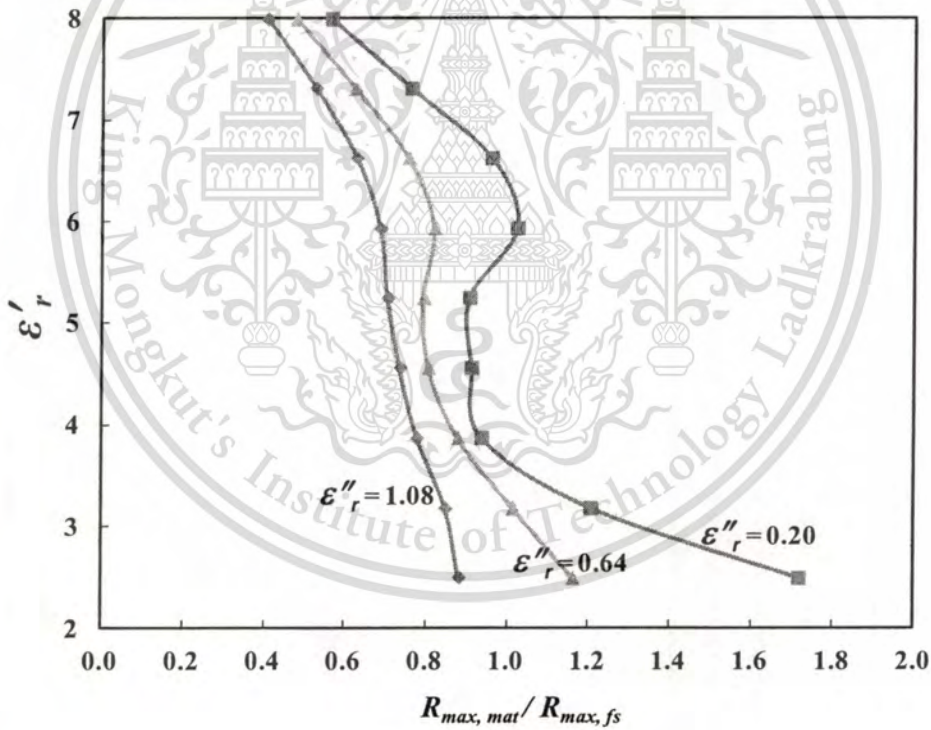

For this case, only  $\epsilon'_r$  of the lossless LWC under test is required ( $\epsilon''_r=0$ ). It will be shown that only one SDT is sufficient to uniquely determine  $\epsilon'_r$  from the measurements of associated read ranges. Fig. 3.9 illustrates the plot of  $\epsilon_r = \epsilon'_r$  versus  $R_{\max,mat}/R_{\max,fs}$  for the SDT<sub>LL</sub>, obtained from the simulation by using (3.6), where  $R_{\max,fs}$  is a normalization constant. As expected from Fig. 3.5 and Fig. 3.9,  $R_{\max,mat}/R_{\max,fs}$  monotonically decreases as  $\epsilon_r$  increases. It is clear from Fig. 3.9 that once  $R_{\max,mat}/R_{\max,fs}$  of the SDT<sub>LL</sub> attached to the lossless LWC under test is known from the measurements, its  $\epsilon_r$  can be uniquely estimated using Fig. 3.9.

**Figure 3.9** The relation between  $\epsilon_r$  and  $R_{\max,mat}/R_{\max,fs}$  for the SDT<sub>LL</sub> obtained from the simulations

### 3.4.2 Lossy Case

Figure 3.10 shows the plot of  $\varepsilon_r = \varepsilon_r'$  versus  $R_{\max, \text{mat}}/R_{\max, \text{fs}}$  for the SDT<sub>1</sub> and SDT<sub>2</sub> with  $\varepsilon_r'' = 0.20, 0.64$  and  $1.08$  obtained from the simulation. It is found that  $\tau_{\text{mat}}$  tends to increase as  $\varepsilon_r'$  increases as expected due to less impedance mismatch, and  $G_{\text{tag, mat}}$  tends to increase and then decrease as  $\varepsilon_r'$  increases. It can be concluded from these two cases (lossless and lossy cases) that an SDT, specifically designed for an LWC with  $\varepsilon_r = \tilde{\varepsilon}_r' - j\tilde{\varepsilon}_r''$ , usually possesses the maximum  $\tau_{\text{mat}}$  when  $\varepsilon_r' = \tilde{\varepsilon}_r'$  and  $\varepsilon_r'' = \tilde{\varepsilon}_r''$ . However, the associated  $G_{\text{tag, mat}}$  is not always the maximum. In addition, this case is a realistic situation that it can be used to determine the dielectric constant of material under test in chapter 5.

(a)

**Figure 3.10** The relation between  $\epsilon'_r$  and  $R_{\max,mat}/R_{\max,fs}$  for the SDT<sub>1</sub> and the SDT<sub>2</sub> with  $\epsilon''_r = 0.20, 0.64$  and  $1.08$  obtained from the simulations

- (b) The relation between  $\epsilon'_r$  and  $R_{\max,mat}/R_{\max,fs}$  for the SDT<sub>2</sub>.

### 3.5 Sensitivity Analysis

To convenient, in practice, the error of tag location mount on LWC is important. Therefore, the effects of SDT location mounted on LWC are studied in terms of the SDT antenna performances. Furthermore, the tolerance of the SDT is also discussed to analyze the sensitivity of the novel RFID sensor.

The sensitivity of a novel RFID sensor technique can be separated into 2 parts as follow:

### 3.5.1 Location Error

The folded dipole with an inductive loop tag antenna is used as an SDT to study effects of location on the lossy LWC. In this study, the LWC has dimension of 200 mm  $\times$  150 mm  $\times$  75 mm with the dielectric property of  $2.5-j0.2$   $\Omega$  at 922.5 MHz is employed. Note that the SDT is obtained by optimizing its dimension to almost conjugately match with the chip impedance of  $16.5-j148.7$   $\Omega$  in the presence of the lossy LWC, where the SDT is mounted of the location  $L_8$  as shown in Fig. 3.11. The LWC surface area is divided into 15 parts for mounting the SDT. Due to the problem symmetry, only the location  $L_1, L_2, L_4, L_5, L_7, L_8, L_{10}, L_{11}, L_{13}$  and  $L_{14}$  are considered.

**Figure 3.11** The location of the SDT on the lossy LWC

Figure 3.12 shows the SDT input impedance as a function of the SDT location  $L_n$ . It is found that the SDT input impedances are similar for location pair as follows:  $(L_1, L_{13}), (L_2, L_{14}), (L_4, L_{10})$  and  $(L_5, L_{11})$ . This is due to the fact that back listed pair

possesses almost the same electromagnetic environment for the SDT. In addition, it is observed that the SDT locations  $L_5$ ,  $L_8$  and  $L_{11}$  yield similar SDT input impedance.

(a) Resistance

(b) Reactance

**Figure 3.12** The input impedance of the SDT mounting on the LWC surface as a function of the SDT Location ( $L_n$ )

The SDT antenna gain as a function of the SDT location  $L_n$  is illustrated in Fig. 3.13. Note that the gain varies strongly with  $L_n$ . It is found that the gains are similar for each location pair as follows:  $(L_1, L_{13})$  and  $(L_2, L_{14})$ . Figure 3.14 illustrates the radiation pattern of the SDT antenna located at  $L_1$  and  $L_{13}$ . It is found that the radiation patterns in the  $xz$ -plane are similar for both locations. However, the radiation patterns in the  $yz$ -plane are noticeably different. In addition, Figure 3.15 shows similar plot as in Fig. 3.14 for the locations  $L_5, L_8$  and  $L_{11}$ . Note that the radiation patterns in the  $xz$ -plane are similar for all locations. However, the radiation patterns in the  $yz$ -plane are noticeably different.

**Figure 3.13** The SDT antenna gain as a function of the SDT location ( $L_n$ )

(a) xz-plane

(b) yz-plane

**Figure 3.14** Comparison of radiation patterns of the SDT antenna for  $L_1$  and  $L_{13}$

**Figure 3.15** Comparison of radiation patterns of the SDT antenna for  $L_5$ ,  $L_8$  and  $L_{11}$

From the results incorporated with equation (3.2) implied that the read range  $R_{max,mat}$  depends on the SDT location on the LWC under test. Recommended SDT location, in practices, is flexible for mounted on the LWC under test.

### 3.5.2 Tolerance

This section presents the effect of SDT tolerance on the tag performances such as the input impedance, the power transmission coefficient, the tag gain and maximum read range. The SDT structure is shown in Fig. 3.16. And the SDT parameters and characteristics are tabulated in Table 3.5 and Table 3.6, respectively.

Figure 3.16 The SDT Structure

Table 3.5 Tag parameters.

Parameter	Dimension (mm)	Parameter	Dimension (mm)
$a_1$	12	$b_4$	23
$a_2$	5	$L$	39.5
$a_3$	17.5	$s_1$	6
$a_4$	4.5	$s_2$	1.75
$a_5$	37.5	$s_3$	5.5
$b_1$	12	$s_4$	2.5
$b_2$	1.5	$W$	25
$b_3$	19.5		

**Table 3.6** SDT Characteristics

SDT Characteristic	Value
Input impedance ( $\Omega$ )	$14.09 + j149.41$
$G_{tag,mat}$ (dBi)	-8.66
$\tau_{mat}$ (%)	99.33
Polarization	Linear

Figure 3.17 to Figure 3.32 shows the input impedance, the power transmission coefficient, SDT gain and maximum read range as a function of SDT parameters. From the results, it is found that the power transmission coefficient decrease when the impedance mismatch. Note that the SDT is optimized its dimension to almost conjugately match with the chip impedance of  $16.5 - j148.7 \Omega$ . Moreover, the comparison of the maximum read range is exhibited in Fig. 3.33 that it is obvious that parameter  $s_3$  is important effect to the maximum read range of an SDT sensor.

### 3.6 Summary

A novel RFID sensor technique operating in the UHF band is designed and analyzed to employ as a remotely read dielectric-property sensors to determine quality of certain CMs through their estimated dielectric properties. It is an NDT technique that does not require additional specific sensors to determine dielectric properties of the materials under test, thereby more convenient in fabrication and usually of lower cost. In addition, the relation between dielectric constant and maximum read range ( $R_{\max}$ ) is illustrated, which it is used to determine material quality in manufacturing and/ or material testing and inspection process. The location error and the tolerance of a novel RFID sensor are analyzed. It is obvious that the characteristics of the SDT antenna depend on tag location on the LWC, especially near the corners and edges of the LWC. However, the SDT characteristics at near center area of the LWC under test ( $L_5$ ,  $L_8$  and  $L_{11}$ ) can be obtained the same results. In practice, the location of SDT is flexible for mounted at LWC in RFID sensor applications. Furthermore, the tolerance analysis is implied that the some SDT parameters are important affected to the maximum read range, especially parameter  $s_3$ .

## CHAPTER 4

# ANTENNA MEASUREMENT

### 4.1 Introduction

From the simulation and analysis of the proposed annular plate antenna with curved and rectangular slots on vertical ground plane is investigated in Chapter 2. This chapter discusses the antenna fabrication and the antenna characteristic measurements to verify the proposed antenna design. The prototype of the annular plate antenna with curved and rectangular slots on vertical ground plane that the optimum parameters are mentioned in previous chapter were fabricated. The antenna measurements were set up to test the antenna characteristics including the radiation patterns in both xz-plane and yz-plane and the antenna gains are also tested. The magnitude of  $S_{11}$  is tested by using the Network Analyzer.

### 4.2 Antenna Fabrication

To verify the antenna characteristics such as the radiation pattern and gain, the experiment was set up at the frequencies of 922.5 MHz and 2.45 GHz for UHF and microwave band of the RFID system. The dimensions of the prototype of the annular plate antenna with curved and rectangular slots on vertical ground plane are tabulated in Table. 4.1.

The fabricated antenna consists of two parts of conductors; first one is the annular plate with curved and rectangular slots as shown in Fig. 4.1 and the other one is the vertical ground plane as shown in Fig. 4.2. The proposed annular plate antenna with curved and rectangular slots on vertical ground plane was fabricated as illustrated in Fig. 4.3. This antenna is fed by using the single probe that made of the metallic conductor is

connected via N-type connector to feed the annular plate with curved and rectangular slots radiating part.

**Table 4.1** Antenna dimension used for fabrication

Parameter	Dimension (mm)
Radius of annular plate ( $a$ )	83.5
Spacing between annular plate and ground plane ( $h_1$ )	7.5
Height of vertical ground plane in x-axis ( $h_2$ )	40
Height of vertical ground plane in y-axis ( $h_3$ )	50
Width of ground plane ( $g_x$ )	187.5
Length of ground plane ( $g_y$ )	225.5
Length of rectangular slot ( $L_s$ )	49.5
Radius of curved slot ( $r$ )	72.5
Radius of circular slot ( $S_1$ )	18
Width of curved slot ( $s_s$ )	11.5
Width of rectangular slot ( $W_s$ )	2
Spacing between rectangular slot and y-axis ( $x_1$ )	25
Spacing between the center of rectangular slot and x-axis ( $y_1$ )	14.5
Location of feeding in y-axis ( $y_p$ )	26
Length of curved slot ( $\phi_1$ )	100°
Angle between the center of curved slot and y-axis ( $\phi_2$ )	90°

**Figure 4.1** The radiating part of the annular plate antenna with curved and rectangular slots on vertical ground plane

**Figure 4.2** The part of vertical ground plane

**Figure 4.3** Photograph of the annular plate antenna with curved and rectangular slots on vertical ground plane

#### 4.3 Magnitude of $S_{11}$ ( $|S_{11}|$ )

To measure the magnitude of  $S_{11}$  of the proposed antenna, the experiment is set up as shown in Fig. 4.4. Figure 4.5 illustrates the comparison between the simulated and measured results of frequency characteristics of magnitude of  $S_{11}$ . It is obvious that the simulated results have the same trend with the experimental ones. However, the experimental and simulated results are different in that bandwidth. The experimental result in microwave band is wider than the simulated one. The magnitude of  $S_{11}$  is better than -10 dB from 912 MHz to 925 MHz (13 MHz) and from 2.32 GHz to 2.69 GHz (360 MHz) as shown in Fig. 4.5. Therefore, it can be operated across the UHF and microwave bands in the RFID system.

## Network Analyzer

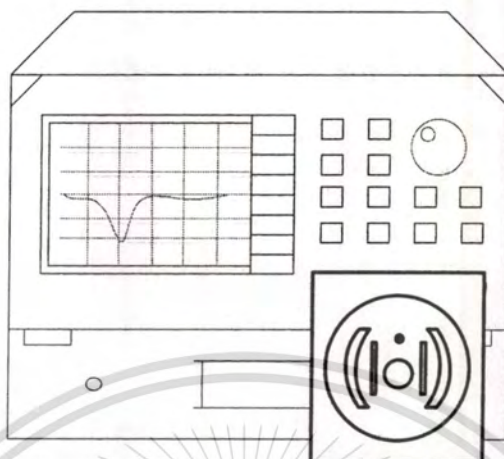

Figure 4.4 Measurement setup of the magnitude of  $S_{11}$

Figure 4.5 Frequency characteristics of magnitude of  $S_{11}$

#### 4.4 Radiation Pattern

The experiments of the radiation pattern need the equipment as follow:

1. The annular plate antenna with curved and rectangular slots on vertical ground plane is shown in Fig. 4.3.
2. The dipole antenna operates in UHF and microwave bands.
3. Network Analyzer (Model: hp 8720C) can operate from 50 MHz to 20 GHz.

For the experiment of radiation pattern, the dipole antenna was employed as transmitting antenna, and the annular plate antenna with curved and rectangular slots on vertical ground plane was rotated to receive the transmitted wave at  $10^\circ$  per step from  $0^\circ$  to  $360^\circ$ . Note that the distance between the transmitting and receiving antennas can be expressed as follow:

$$R = \frac{2D^2}{\lambda}, \quad (4.1)$$

where  $R$  is Far-field region

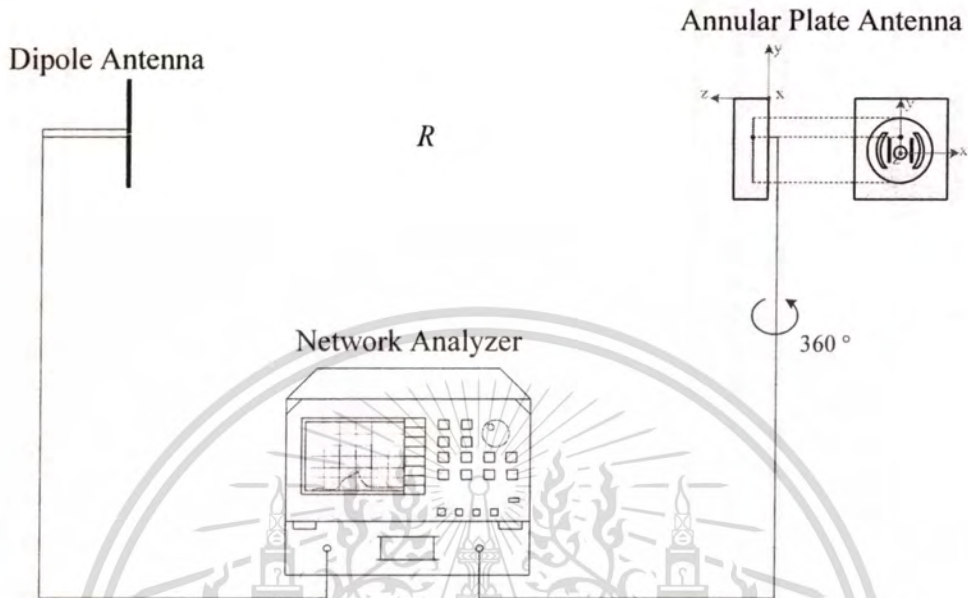

$D$  is a maximum overall dimension of 28.4 cm

$\lambda$  is wavelength of 2.45 GHz.

When substituted into (4.1), the far-field range in free space is yielded as 132 cm. In this section, the far-field region of 200 cm is used.

To measure the radiation pattern of the annular plate antenna with curved and rectangular slots on vertical ground plane, the measurement set up to test the co-polarized pattern and cross-polarized pattern in  $xz$ -plane are depicted in Fig. 4.6 and Fig. 4.7, respectively. After that the measurement also set up to test the co-polarized pattern and cross-polarized pattern in  $yz$ -plane are depicted in Fig. 4.8 and Fig. 4.9, respectively.

1. The measurement set up of the co-polarized pattern in  $xz$ -plane is illustrated in Fig. 4.6.

**Figure 4.6** Measurement setup of the co-polarized pattern in  $xz$ -plane

2. The measurement set up of the cross-polarized pattern in  $xz$ -plane is illustrated in Fig. 4.7.

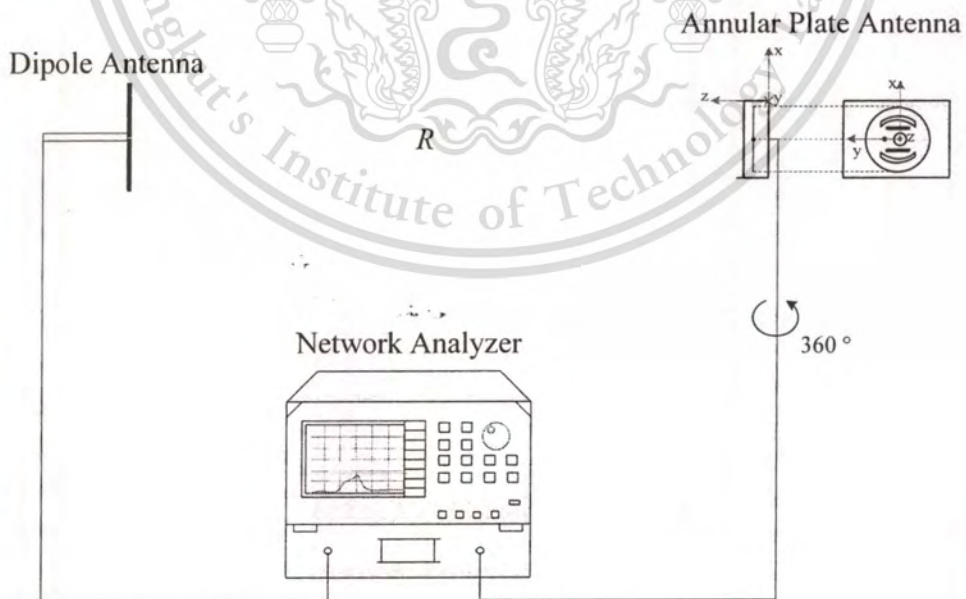

**Figure 4.7** Measurement setup of the cross-polarized pattern in  $xz$ -plane

3. The measurement set up of the co-polarized pattern in  $yz$ -plane is illustrated in Fig. 4.8.

**Figure 4.8** Measurement setup of the co-polarized pattern in  $yz$ -plane

4. The measurement set up of the cross-polarized pattern in  $yz$ -plane is illustrated in Fig. 4.9.

**Figure 4.9** Measurement setup of the cross-polarized pattern in  $yz$ -plane

**Figure 4.10** Radiation patterns at the frequency of 922.5 MHz (a) xz-plane and (b) yz-plane

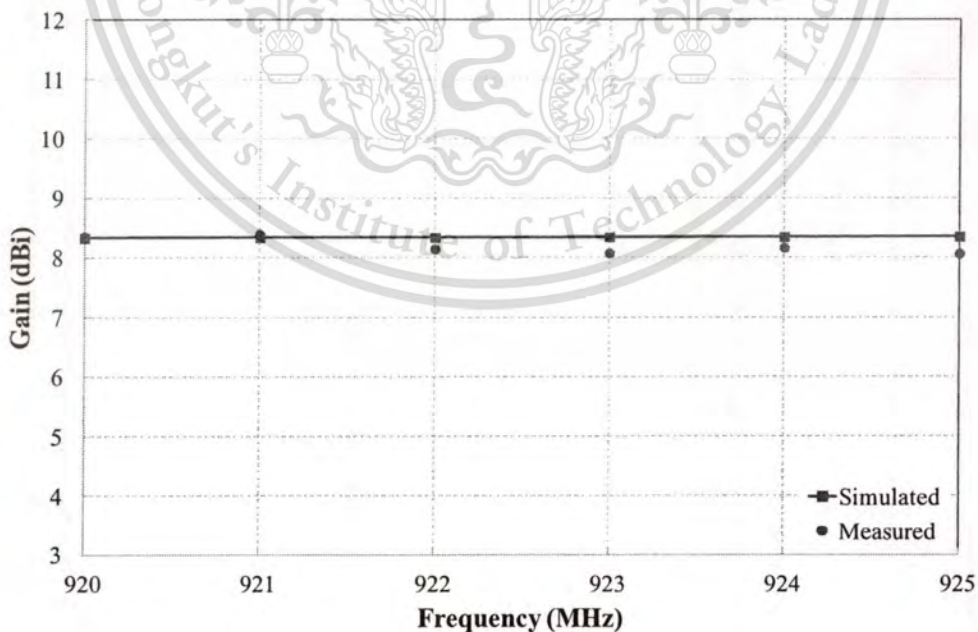

**Figure 4.11** Radiation patterns at the frequency of 2.45 GHz (a) xz-plane and (b) yz-plane

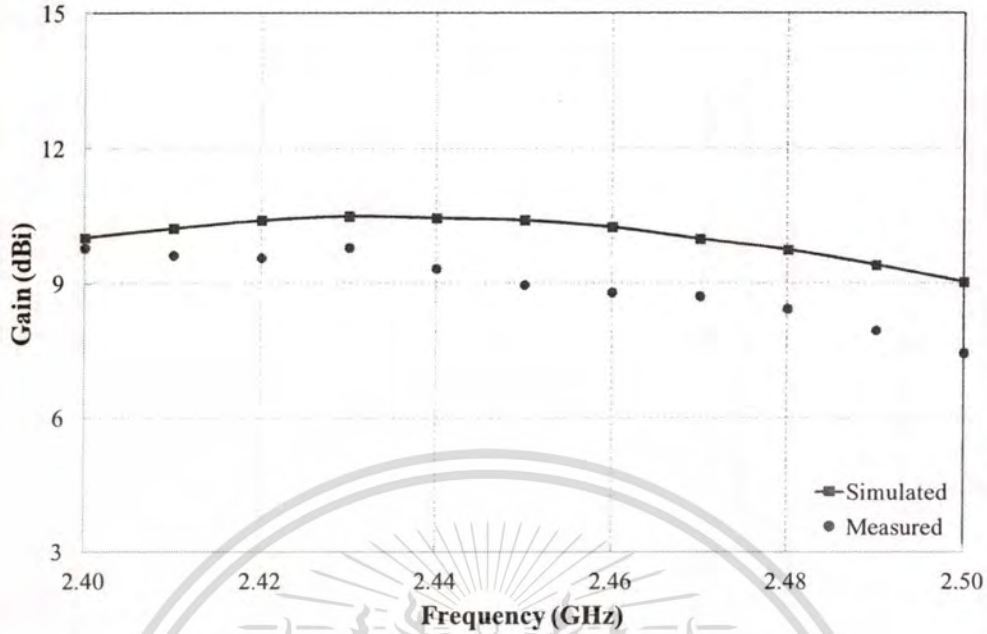

Experimental results of the radiation pattern in  $xz$ -plane and  $yz$ -plane at 922.5 MHz and 2.45 GHz are plotted and compared with the simulation results as shown in Fig. 4.10 and Fig. 4.11, respectively. From the results, it is found that these results are in good agreement. The radiation patterns for both of 922.5 MHz and 2.45 GHz are unidirectional beam with a half-power beamwidth in  $xz$ -plane and  $yz$ -plane of  $80^\circ$  and  $50^\circ$  at the frequency of 922.5 MHz. At the frequency of 2.45 GHz, the half-power beamwidths in  $xz$ -plane and  $yz$ -plane are  $35^\circ$  and  $10^\circ$ , respectively.

#### 4.5 Antenna Gain

The measured gains of proposed annular plate antenna with curved and rectangular slots on vertical ground plane in the UHF band from 920 MHz to 925 MHz and the microwave band from 2.4 GHz to 2.5 GHz are illustrated and compared with the simulation results in Fig. 27. It is found that the simulated and measured gains have similar trend. Moreover, the measured gains at the beam peak direction ( $0^\circ$  in  $xz$ -plane and  $yz$ -plane) at the center frequency of 922.5 MHz and 2.45 GHz in UHF and microwave band are 8.3 dBi and 9 dBi, respectively.

**Figure 4.13** Antenna gain (a) UHF band and (b) Microwave band

#### 4.6 Summary

The experiments of magnitude of  $S_{11}$ , the radiation pattern and antenna gain were setup to verify the antenna characteristics that are simulated by using the electromagnetic simulation program. It is found that the simulation and measurement results are agreed very well. The prototype of the annular plate antenna with curved and rectangular slots on vertical ground plane can be operated across both frequencies of UHF and microwave band in RFID applications. The bandwidths cover from 912 MHz to 925 MHz which is 1.4 % and from 2.32 GHz to 2.69 GHz which is 14.7 %. The proposed antenna radiates the unidirectional pattern in both bands. The half-power beamwidths in  $xz$ - and  $yz$ -plane are 80 degree and 50 degree of 922.5 MHz, respectively. At 2.45 GHz, the half-power beamwidths in  $xz$ - and  $yz$ -plane are 35 degree and 10 degree, respectively. In addition, the antenna gains are 8.3 dBi in the UHF band and from 7.5 dBi to 10 dBi in microwave band. These results exhibit that the proposed antenna can work well in the practical situation and can be used for RFID reader.

## CHAPTER 5

# APPLICATION FOR DETERMINATION OF MATERIAL PROPERTY

### 5.1 Introduction

In this chapter, a series of measurements is performed to measure read ranges of the passive RFID sensor system for an LWC as an example of CMPs, and these measured read ranges will be processed appropriately to inversely determine the dielectric constant of the LWC under test, which in turn provides information on its qualities. A dielectric-constant determination procedure of material under test is investigated using the dependency of the read range of the passive RF identification (RFID) sensor system on the electromagnetic properties of CMPs near or in contact with RFID tags, the qualities of CMPs can be determined through their estimated dielectric properties.

### 5.2 Read Range Measurement

**Figure 5.1** The novel RFID sensor setup

The read range between the RFID reader and the SDTs attached to the LWC of interest are measured in an anechoic chamber as illustrated in Fig. 5.1. The prototypes of the SDT<sub>1</sub> and the SDT<sub>2</sub> are a printed meander line with a coupling loop on the FR4 substrate as shown in Fig. 5.2. To measure the maximum read range, the SDT is attached to the LWC under test as shown in Fig. 5.3.

Since the maximum distance ( $R_{max, mat}$ ) is calculated by using the modified Friis transmission equation, under assumption that the reader antenna has perfect impedance matching and perfect polarization matching to the tag antenna and the preliminary parameters as determined in chapter 3. Thus, to verify the methodology of determination of dielectric property of material of interest, the dipole antenna is first employed as the transmitting antenna. Note that the linear polarization is acquired.

Subsequently, replace the dipole antenna with the annular plate antenna with curved and rectangular slots on vertical ground plane to transmit wave.

(a)

(b)

**Figure 5.2** The SDT prototypes. (a) SDT<sub>1</sub> for the dry LWC. (b) SDT<sub>2</sub> for the saturated LWC

**Figure 5.3** The photograph of an SDT attached to the LWC of interest

The experiment of read range, to determine the dielectric property of material of interest, is required the equipment as follow:

1. The SDTs are shown in Fig. 5.2.
2. The dipole antenna is employed as transmitting antenna as illustrated in Fig. 5.4.
3. The annular plate antenna with curved and rectangular slots on vertical ground plane is employed as transmitting antenna as shown in Fig. 5.5.
4. UHF RFID Reader Model: Motorola XR450 is shown in Fig. 5.6.
5. Computer
6. Coaxial Cable

**Figure 5.4** The dipole antenna

**Figure 5.5** The annular plate antenna with curved and rectangular slots on vertical ground plane

**Figure 5.6** UHF RFID Reader Model: Motorola XR450

**Figure 5.7** The RFID sensor measurement setup in an anechoic chamber, when the dipole antenna is employed as transmitting antenna

**Figure 5.8** The RFID sensor measurement setup in an anechoic chamber, when the annular plate antenna with curved and rectangular slots on vertical ground plane is employed as transmitting antenna

From measurements, the read ranges of SDTs attached to lossy LWCs under test can be calculated and are shown in Table 5.1. The read ranges from the simulations and measurements agree reasonably well. The discrepancies between the simulated and

measured results may derive from the measurement error and the SDT fabrication error. Therefore, the measured read range can be used to inversely determine the dielectric constant of LWCs under test with reasonable accuracy.

**Table 5.1** Read range of SDTs attached to lossy LWCs under test, when the dipole antenna is transmitting antenna.

LWC State	Simulation (cm)	Measurement (cm)
Dry	68.3	69
Saturated	54.7	50

### 5.3 Dielectric-Constant Determination Procedure

Once the read ranges of all SDTs attached to the LWC under test are known via measurements, including the corresponding read ranges of the SDTs in the free space, the dielectric constant of the LWC under test can be determined from the following procedure.

For the lossy LWC case, both  $\epsilon_r'$  and  $\epsilon_r''$  of the lossy LWC under test are required. It will be shown that two SDTs are required to uniquely determine both  $\epsilon_r'$  and  $\epsilon_r''$  from the measurements of associated read ranges. In this study, the SDT<sub>1</sub> and the SDT<sub>2</sub>, specifically designed for the dry and saturated LWC states respectively, are attached to the lossy LWC under test. Using the simulations, the plot of  $\epsilon_r'$  versus  $R_{\max,mat}/R_{\max,fs}$  for each SDT is illustrated in Fig. 5.9 for  $\epsilon_r'' = 0.20, 0.64$  and  $1.08$ . It is clearly seen from Fig. 5.9 that either SDT<sub>1</sub> or SDT<sub>2</sub> alone cannot be employed to uniquely determine  $\epsilon_r'$  and  $\epsilon_r''$  from a measurement of  $R_{\max,mat}/R_{\max,fs}$  since several combinations of  $\epsilon_r'$  and  $\epsilon_r''$  yield the same  $R_{\max,mat}/R_{\max,fs}$ . However, using both SDT<sub>1</sub> and SDT<sub>2</sub> with a measurement of  $R_{\max,mat}/R_{\max,fs}$  for each SDT,  $\epsilon_r'$  and  $\epsilon_r''$  can be determined uniquely as shown in the following three examples.

Consider a sample of lossy LWCs (sample#1) as shown in Fig. 5.9(a), where its dielectric constant  $\epsilon_r$  is equal to  $7.5-j1.08$  obtained from the dielectric probe measurement, which requires a network analyzer. From the read range measurements, it

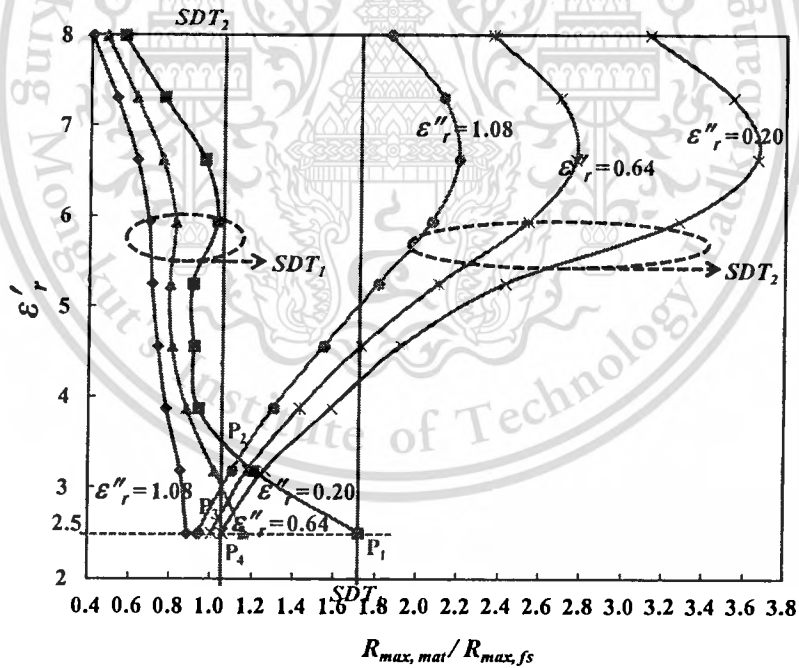

is found that  $R_{\max,mat}/R_{\max,fs}$  for the  $SDT_1$  and the  $SDT_2$  are equal to 0.5 and 2.10 respectively, as shown in Fig. 5.9(a) as the two vertical lines. It should be pointed out that the maximum distances  $R_{\max,fs}$  of each SDT are generally different. In Fig. 5.9(a), each vertical line of  $R_{\max,mat}/R_{\max,fs}$  intersects the family of the relation between  $\epsilon'_r - R_{\max,mat}/R_{\max,fs}$  curves for each SDT at  $P_1$  and  $P_2$  for the  $SDT_1$  and  $P_3, P_4, P_5$  and  $P_6$  for the  $SDT_2$ . At each intersection point, a pair of  $\epsilon'_r$  and  $\epsilon''_r$  is obtained. Due to the fact that the sample of lossy LWCs is identical for both  $SDT_1$  and  $SDT_2$ , only the intersection points, providing the identical pair of  $\epsilon'_r$  and  $\epsilon''_r$ , are valid. It can be seen from Fig. 5.9(a) that the intersection points  $P_1$  and  $P_3$  correspond to  $(\epsilon'_r, \epsilon''_r) = (7.40, 1.08)$ , which is the estimated dielectric constant of the LWC sample#1.

(a) The LWC sample#1

(b) The LWC sample#2

(c) The LWC sample#3

**Figure 5.9** The relation between  $\epsilon'_r$  and  $R_{max,mat}/R_{max,fs}$  for the  $SDT_1$  and the  $SDT_2$  with  $\epsilon''_r = 0.20, 0.64$  and  $1.08$  obtained from the simulations

Consider another sample of lossy LWCs (sample#2), where its dielectric constant  $\epsilon_r$  is equal to  $4.8-j0.4$  obtained from the dielectric probe measurement. Using the same determination procedure as in the case of the LWC sample#1,  $R_{\max,mat}/R_{\max,fs}$  for the SDT<sub>1</sub> and the SDT<sub>2</sub> are found to be 0.77 and 1.77 respectively, as shown in Fig. 5.9(b) as the two vertical lines. It can be seen from this figure that the intersection points P<sub>4</sub> and P<sub>7</sub> correspond to  $(\epsilon'_r, \epsilon''_r) = (4.70, 0.64)$ , which is the estimated dielectric constant of the LWC sample#2.

For the last example, let us consider the sample of lossy LWCs (sample#3), where its dielectric constant  $\epsilon_r$  is equal to  $2.5-j0.2$  also obtained from the dielectric probe measurement. Using the same determination procedure as in the case of the LWC sample#1,  $R_{\max,mat}/R_{\max,fs}$  for the SDT<sub>1</sub> and the SDT<sub>2</sub> are found to be 1.71 and 1.05 respectively, as shown in Fig. 5.9(c) as the two vertical lines. It can be seen from this figure that the intersection points P<sub>1</sub> and P<sub>4</sub> correspond to  $(\epsilon'_r, \epsilon''_r) = (2.5, 0.2)$ , which is the estimated dielectric constant of the LWC sample#3.

Thus, two SDTs can be employed to uniquely determine the dielectric constant of the lossy LWC under test. For these examples, the relative error of 1.3%, 5.4 % and 0 % for sample#1, sample#2 and sample#3, respectively, can be obtained using the novel RFID sensor, which is reasonably accurate. It should be pointed out that the relative error can be decreased by reducing the measurement error of associated read ranges and the SDT fabrication error. It is important to note that the dielectric constant of sample#3 is also obtained with 0 % by using the dipole antenna. For this reason, the annular plate antenna with curved and rectangular slots on vertical ground plane can be used as an RFID reader antenna in a novel RFID sensor to determine the dielectric property of material under test. Once the dielectric constant of the LWC sample is estimated, the quality of the LWC sample can be determined by using the relation between the dielectric constant and the LWC quality, predetermined by measurements and testings or other approaches [53]-[55].

## 5.4 Summary

The promising approach based on a novel RFID sensor is successfully employed to determine the dielectric property of LWC samples through associated read-range measurements. The dielectric-constant determination procedure for lossy LWCs is discussed in detail in this chapter. It is found that the novel RFID sensor provides reasonably accurate results. Note that to use this RFID sensor, it is necessary to know size and shape of material under test, and then perform simulation for desired size and shape first. Furthermore, the annular plate antenna with curved and rectangular slots on vertical ground plane is designed in the previous chapter that can be employed as a reader antenna in a novel RFID sensor.

## CHAPTER 6

# CONCLUSION

### 6.1 Summary of Preceding Chapters

As mentioned in the first chapter, this thesis proposes a determination of dielectric property of material of interest using a novel RFID sensor. This procedure is categorized into NDT technique. The benefits is based on using this technique that the novel RFID sensor does not require additional specific sensors to determine dielectric properties of the materials under test, thereby more convenient in fabrication and usually of lower cost. In addition, the novel RFID sensor does not require a network analyzer and other expensive accessories.

Chapter 2 presents a principle of the antenna design procedure and the simulation to determine the optimum parameters of the annular plate antenna with curved and rectangular slots on vertical ground plane. The proposed antenna can be operated in a dual-band of UHF and microwave bands in RFID applications. The radiation pattern of the antenna appears to be a unidirectional beam in the broadside direction both of frequency bands. In addition, the antenna gain is high because that air substrate is used. Therefore, the proposed antenna can be employed as an RFID reader antenna in a novel RFID sensor system.

In Chapter 3, a novel RFID sensor technique operating in the UHF band is designed and analyzed to employ as a remotely read dielectric-property sensors to determine quality of certain CMs through their estimated dielectric properties. The relation between dielectric constant and maximum read range ( $R_{\max}$ ) is illustrated, which it is used to determine material. Moreover, the sensitivity of the novel RFID sensor on the location error and the tolerance are discussed and analyzed in this chapter.

Chapter 4 verifies the principle and theory presented in the chapter 2. The antenna prototype is fabricated with the optimum parameters to test its characteristics. The experiments of magnitude of  $S_{11}$ , the radiation pattern and antenna gain were setup. It is found that the simulation and measurement results are agreed very well. These results corroborate that the proposed antenna can be used as an RFID reader.

Chapter 5 corroborates a determination of dielectric property of material under test using a novel RFID sensor. The dielectric-constant determination procedure for lossy LWCs is performed and discussed. It is found that the novel RFID sensor provides reasonably accurate results. Furthermore, the annular plate antenna with curved and rectangular slots on vertical ground plane is designed in the previous chapter that can be employed as a reader antenna in a novel RFID sensor.

Finally, the summary of this thesis and the remark for the future studies are included in chapter 6.

## 6.2 Remark for Future Studies

In this thesis, the determination of dielectric property of LWC using a novel RFID sensor is investigated and analyzed. However, this technique is based on the modified Friis transmission equation under the assumption that the reader antenna has perfect impedance matching and perfect polarization matching to the tag antenna. To be more accurate, hence, these hypotheses should be taken into account when calculating the maximum read range.

In addition, this thesis is mentioned on the development of a reliable sensor technique to determine material quality in manufacturing and/ or material testing and inspection process. The LWC is employed as an example of CMPs that is assumed to be a homogeneous. This is left for further works.

Further works include reducing associated errors of estimating the dielectric constant of CMPs and other interest materials. In addition, effects of sizes and shapes of materials under test will also be studied based on the same sensor principle, including the practical approaches to mount SDTs on these materials.

# VITA

Rattapong Suwalak was born in Songkhla, Thailand, on 23 August 1982. He received the B. Eng. degrees in Electrical Engineering from the Department of Electrical Engineering, Faculty of Engineering, Prince of Songkla University (PSU), Songkhla, Thailand, in 2005. After one year, he entered the department of Telecommunications Engineering, Faculty of Engineering, King Mongkut's Institute of Technology Ladkrabang (KMITL), Bangkok, Thailand, and received the M. Eng. degree in Telecommunication Engineering in 2008. During his study for Ph.D. in Electrical Engineering at KMITL, he received a Thailand Graduate Institute of Science and Technology (TGIST), NSTDA. He was an assist. researcher at National Electronics and Computer Technology Center (NECTEC), Bangkok, Thailand. His research interests include the antenna design for portable and wireless communication, especially, in the RFID technology.
