### ABSTRACT

The structure-properties relationship of barium titanate-based system were studied in this work. To study piezoelectric properties, the design of two phases or multiphase near room temperature in BaTiO<sub>3</sub>-based was focused in this work. Ternary system of BaTiO<sub>3</sub>-SrTiO<sub>3</sub>-BaSnO<sub>3</sub> and BaTiO<sub>3</sub>-Bi<sub>0.5</sub>Na<sub>0.5</sub>TiO<sub>3</sub>-Bi(Mg<sub>0.5</sub>Ti<sub>0.5</sub>)O<sub>3</sub> were selected for investigation. The ceramics of (0.975-y)BaTiO<sub>3</sub>-0.025SrTiO<sub>3</sub>-yBaSnO<sub>3</sub> (abbreviated as BT-ST-yBS) with y = 0.00, 0.02, 0.04, 0.06, 0.08 and 0.10 were synthesized via conventional solid state reaction. This system was carried out to study the effect of Sn on the crystal structure, phase transition, dielectric, ferroelectric, and piezoelectric properties of BT-ST-yBS ceramics. A room temperature, the composition y = 0.04 exhibited multi-coexistence phase which shows high relative permittivity ( $\epsilon_r$ ) of 11500 and high reversible strain of 0.12% with the normalized piezoelectric coefficient ( $S_{max}/E_{max}$ ) of 1,280 pm/V at a low electric field (10 kV/mm).

In the second system, the 0.9BaTiO<sub>3</sub>-(0.1-x)Bi<sub>0.5</sub>Na<sub>0.5</sub>TiO<sub>3</sub>-xBi(Mg<sub>0.5</sub>Ti<sub>0.5</sub>)O<sub>3</sub> (abbreviated as BT-BNT-xBMT) ceramic, x = 0.00, 0.02, 0.04, 0.06, 0.08 and 0.10, were prepared. The effect of BMT on crystal structure, phase transition, morphology, dielectric, ferroelectric, and piezoelectric properties of BT-BNT ceramics were studied as a function of composition. The crystal structure of BT-BNT-xBMT successively transforms from tetragonal to pseudocubic symmetry, with increased BMT content. Temperature dependence of dielectric constant ( $\epsilon_r$ ) and dielectric loss ( $\tan\delta$ ) for BT-

BNT-xBMT at various frequencies showed that phase transition of ceramics changed from ferroelectric to relaxor-like behavior as BMT content increased. Furthermore, remanent polarization ( $P_r$ ), coercive field ( $E_c$ ) and the normalized strain ( $d_{33}^*$ ) of BT-BNT-xBMT ceramics tend to decrease with increasing BMT concentration.

**Keywords :** Lead-free piezoelectric materials, Barium titanate, Solid state reaction

## ACKNOWLEDGMENT

This thesis has been accomplished in the Electroceramic Research Laboratory, College of Nanotechnology, King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand.

Throughout the period of 4 years ago in master's degree, I must acknowledge many people who have great assistance me. First, I would like to thank my co-advisor, Assoc. Prof. Dr. Naratip Vittayakorn who has guided me through these years for all invaluable advices, inspiration and supports throughout my education. I would like also to thank my advisor, Asst. Prof. Dr. Wanwilai Vittayakorn who has all the supports, kind advices and encourage in this study

I would like to thank to thank my committee members, Assoc. Prof. Dr. Wisanu Pecharapa, Asst. Prof. Dr. Thutiyaporn Thiwawong and Dr. Usa Sukkha, for their comment, valuable advices and questions.

I am grateful to Assist. Prof. Dr. Soodkhet Pojprapai and Asst. Prof. Dr. Theerachai Bongkarn, is credited for piezoelectric measurement, Dr. Rangson Muanghlua, Department of Electronics, Faculty of Engineering, King Mongkut's Institute of Technology Ladkrabang, is credited for dielectric measurement.

Addition, I wish to thank ECRL members for all helps, assistance and encourage me.

Finally, I would like to express my deepest thanks to my family, my father, Adun Mayamae, my mother, Kannika Mayamae, , my old sister, Aksara Mayamae, and my old brother, Kittikhun Mayamae, who have always encourage, helps, assistance and support me in everything until through all the difficulties during my studied.

Jitkasem Mayamae

# CHAPTER 1

## INTRODUCTION

### 1.1 Overview

Piezoelectric materials have been studied widely and used extensively in many electronic devices such as electromechanical transducers, sensors and actuators, due to their excellent ferroelectric and piezoelectric properties [1]. It is known that Lead – based piezoelectric materials, for example, lead zirconate titanate (PZT) and PZT – family have been used widely in many piezoelectric applications [2]. However, lead – based piezoelectric materials contain over 60 wt% of lead, which is a serious threat to the environment. The fabrication process of these materials also uses lead oxide, which enhances toxicity further due to volatilization at a high temperature, predominantly during calcination and the sintering process, thus causing environmental pollution [3]. Consequently, legislations from the European Union (EU), including Restriction of Hazardous Substances (RoHS), Waste from Electrical and Electronic Equipment (WEEE), and End of Life Vehicles (ELV), have been put into effect in order to restrict the use of hazardous substances such as lead and other heavy metals in electronic devices [4–6]. There have been many previous scientific works that have substituted lead-free piezoelectric materials, but the properties used were not nearly as effective as those in the PZT system. Candidate lead – free perovskite systems are fundamentally Barium Titanate ( $\text{BaTiO}_3$ ; BT), Bismuth Sodium Titanate ( $(\text{Bi}_{0.5}\text{Na}_{0.5})\text{TiO}_3$ ) and Potassium Sodium Niobate ( $(\text{K}_{0.5}\text{Na}_{0.5})\text{NbO}_3$ ) ceramics [7].

BT-based ceramics are a lead-free piezoelectric material candidate, due to their outstanding piezoelectric properties [8]. It is known that the coexistence of different ferroelectric phases plays a crucial role in enhancing piezoelectric properties in lead and lead-free piezoelectric properties. The piezoelectric properties of BT ceramic have been modified by doping with either A- and/or B – site substitutions into the  $\text{ABO}_3$  structure. The binary system of tin-doped into barium titanate ( $\text{BaTiO}_3-x\text{BaSnO}_3$ ) recently showed high dielectric permittivity ( $\epsilon_r$ )  $\sim 75,000$  and piezoelectric coefficient ( $d_{33}$ )  $\sim 697$  pC/N at the quasi-quadruple point, at which Cubic, Tetragonal, Orthorhombic and Rhombohedral phases coexist [9]. Xusheng Wang et al. reported a

high electrostriction strain value of  $\sim 0.22\%$  in the binary systems of  $\text{BaTiO}_3\text{-CaTiO}_3$ , where diphasic or tetragonal and orthorhombic phases occur at room temperature [10]. Wei Li et al. investigated the polymorphic phase transition (PPT) from orthorhombic to tetragonal phase in the BT–BZ–CT system, and a high piezoelectric constant ( $d_{33}$ ) of  $\sim 365$  pC/N and planar electromechanical coupling ( $k_p$ ) at  $\sim 48.5\%$  were recorded at the PPT composition [11-12]. Extremely high piezoelectric properties;  $d_{33} = 568$  pC/N,  $k_p = 47.7\%$ ,  $\epsilon_r = 23000$  and normalized strain ( $dS/dE$ ) = 1013 pm/V, were found recently at the orthorhombic-tetragonal coexistence phase composition [13]. The multiphase coexistence of rhombohedral–pseudocubic–orthorhombic phase (R–PC–O) composition exhibited an ultrahigh  $d_{33} = 670$  pC/N at room temperature [14].

Complex perovskite was used also recently to modify the piezoelectric properties of BT ceramics. Wada et al. studied the combination between  $\text{BaTiO}_3$  and  $\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  (BMT) and found that BMT can enhance Curie temperature ( $T_C$ ) of BT with the highest  $T_C$  (about  $360^\circ\text{C}$ ) for  $0.5\text{BaTiO}_3 - 0.5\text{BMT}$  ceramics [15]. Qi Wang et al. studied lead-free  $\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3 - \text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  systems and reported that BMT could improve piezoelectric properties and enhance  $T_C$  of BNT ceramic. The  $0.95\text{BNT} - 0.05\text{BMT}$  ceramic showed the highest  $d_{33}$  at about 110 pC/N, with high  $T_C$  at  $352^\circ\text{C}$  [16].

In this work, the substituting system in BT is classified into two classes; substituting with a simple perovskite ( $\text{ABO}_3$ ) system (such as CT, BS, ST and BSn) and a complex perovskite ( $\text{A}'\text{A}''\text{B}'\text{B}''\text{O}_3$ ) system (such as BMT, BNT, KNN). Based on information from the literature review, the ferroelectric phase diagram of BT–ST–BS and BT–BNT–BMT has been created to explore the effect of substituting with a simple perovskite ( $\text{ABO}_3$ ) system and a complex perovskite ( $\text{A}'\text{A}''\text{B}'\text{B}''\text{O}_3$ ), respectively. Based on the phase diagram, the composition range in the  $(0.975-y)\text{BaTiO}_3 - 0.025\text{SrTiO}_3 - y\text{BaSnO}_3$  (abbreviated as BT–ST–yBS) system and  $0.9\text{BaTiO}_3 - (0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3 - x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  (abbreviated as BT–BNT–xBMT) system is expected to display the multiphase near room temperature. The goal of this study is to synthesize the lead-free piezoelectric ceramics of the barium titanium-based ternary system in two systems:

1. The ternary system of  $(0.975-y)\text{BaTiO}_3-0.025\text{SrTiO}_3-y\text{BaSnO}_3$ , where  $y = 0.00, 0.02, 0.04, 0.06, 0.08$  and  $0.10$ .
2. The ternary system of  $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$ , where  $x = 0.00, 0.02, 0.04, 0.06, 0.08, 0.10$

Based on the PPT concept, high piezoelectric properties are expected to be obtained near the PPT composition. The structure – properties relationship will be studied systematically and explored.

## 1.2 Scope of this work

The goal of this study is to synthesize lead-free piezoelectric ceramics of the barium titanium-based ternary system in two systems. The first system is  $(0.975-y)\text{BaTiO}_3-0.025\text{SrTiO}_3-y\text{BaSnO}_3$ , where  $y = 0.00, 0.02, 0.04, 0.06, 0.08$  and  $0.10$  and the second  $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$ , where  $x = 0.00, 0.02, 0.04, 0.06, 0.08$  and  $0.10$ . These two systems are fabricated via solid state reaction with metal oxide used for starting materials. The effect of cations substitution on crystal structure and phase transition was examined by the X-ray diffraction technique (XRD), dielectric measurement and Raman spectroscopy. The morphology of ceramics was determined using scanning electron microscopy (SEM). Electrical measurements such as dielectric, ferroelectric and piezoelectric properties of ceramics also were investigated.

### 1.3 Objectives of this work

- 1.3.1 To prepare  $(0.975-y)\text{BaTiO}_3-0.025\text{SrTiO}_3-y\text{BaSnO}_3$  and  $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  ceramics by the conventional solid state mixed oxide method.
- 1.3.2 To study effect of the composition on the crystal structure and phase transition as well as electrical properties  $(0.975-y)\text{BaTiO}_3-0.025\text{SrTiO}_3-y\text{BaSnO}_3$  and  $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  ceramics.
- 1.3.3 To study the crystal structure and phase transition of  $(0.975-y)\text{BaTiO}_3-0.025\text{SrTiO}_3-y\text{BaSnO}_3$  and  $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  ceramics by Raman spectra, XRD and dielectric measurement.
- 1.3.4 To study the morphology and grain size of  $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  ceramics by Scanning electron microscope.
- 1.3.5 To investigate the dielectric ferroelectric and piezoelectric properties of  $(0.975-y)\text{BaTiO}_3-0.025\text{SrTiO}_3-y\text{BaSnO}_3$  and  $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  ceramics.

## CHAPTER 2

# LITERATURE REVIEW

### 2.1 Piezoelectricity

The first phenomenon of piezoelectric effect was discovered in 1880 by French physicists Pierre and Jacques Curie in quartz [1]. *Piezo* word is press or squeeze in Greek and electric word is relate to electric charge or electrical energy. Two different of piezoelectricity are direct and indirect effect, which this materials must have switching of both effect. The direct effect or direct piezoelectric effect is the generation of electricity when compression or stress is applied into piezoelectric material as shown in Figure 2.1 (a). The direct effect is used in sensor applications such as gas igniters, accelerometer and microphones, as shown in figure 2.2. Conversely, for indirect effect or converse piezoelectric effect is distortion in the crystal when an electric field is applied (see in Figure 2.1 (b)). These indirect effect is a have been applied in actuator device include liquid inkjet printers, common rail diesel injection, dual – stage actuator in HDDs, and camera shutter, as shown in figure 2.2.

Figure 2.2 Piezoelectric applications [2, 3]

Piezoelectricity is the coupling between electrical and mechanical displacements in a material. The direct and converse piezoelectric effect can be described by basic equations 2.1 and 2.2 respectively [4]

**Direct effect:**

$$D = d_1 T + \epsilon^T E \quad (2.1)$$

where  $D$  is dielectric displacement,  $T$  is the mechanical stress,  $\epsilon^T$  is the permittivity at constant stress,  $E$  is the electric field and  $d_1$  is piezoelectric charge coefficients direct piezoelectric effect.

**Converse effect:**

$$S = s^E T + d_2 E \quad (2.2)$$

where  $S$  is mechanical strain,  $s^E$  is mechanical compliance,  $T$  is mechanical stress,  $E$  is the electric field and  $d_2$  is piezoelectric charge coefficients for converse piezoelectric effect.

Furthermore, the piezoelectric ceramics demonstrate an anisotropic effect. The direction of the induced polarization depends on the direction of the applied electric field or the mechanical force with piezoelectric materials. However, the direction of polarization is conventionally taken as the 3 axis by the Z – axis of a rectangular system. Direction X, Y, or Z is represented by the subscript 1, 2, or 3, respectively, and shear strains about one of these axes is represented by the subscript 4, 5 or 6, respectively [5], as shown in Figure 2.3. Therefore,  $d$  is a tensor and many other physical properties of piezoelectric materials have two subscripts that indicate the directions of two related quantities. For example, piezoelectric constant  $d_{33}$  is measure when the induced polarization is generated in direction 3 due to a stress applied in direction 3 and  $d_{31}$  represents the induced polarization in direction 3 per unit stress applied along direction 1 [4]. High piezoelectric constants are desirable in order to increase the charge or strain developed per force or electric field applied.

Figure 2.3 Directional axes (Modified from [5])

Another important parameter used to describe piezoelectric efficacy is the electromechanical coupling factor ( $k$ ). The  $k$  factor represents the ability of a piezoceramic material from electrical to mechanical form or vice versa and it depends on degree of poling for ceramics [5].

$$k = \sqrt{\frac{\text{input mechanical energy converted into electrical energy}}{\text{input mechanical energy}}} \quad (2.3)$$

$$k = \sqrt{\frac{\text{input electrical energy converted into mechanical energy}}{\text{input electrical energy}}} \quad (2.4)$$

The subscripts denote the relative directions of electrical and mechanical quantities and the kind of motion involved such as  $k_{33}$ ,  $k_{31}$ . For a thin piezoelectric ceramic disc is the planar coupling factor ( $k_p$ ).

The crystals can be divided into these 32 symmetry point groups. Out of these 32 point groups, 21 are noncentrosymmetric with one or more crystallographically unique directional axes and 11 are centrosymmetric (Non-piezoelectric), meaning the centre of positive and negative charge coincides with each other. Out of these 21 point groups, 20 belongs to the class of piezoelectric. Out of these 20 point groups, 10 are pyroelectrics. The ferroelectrics are a subgroup of pyroelectrics [6], as shown in figure 2.4.

Figure 2.4 Relationship of piezoelectricity and its subdivisions with symmetry groups [6]

## 2.2 Ferroelectricity

### 2.2.1 Ferroelectrics

A subgroup ferroelectric are pyroelectric and the sub set of pyroelectric are piezoelectric. Thus relationship between ferroelectrics and piezoelectrics is exhibited in the Venn diagram in figure 2.5. In the year 1921, ferroelectricity was first discovered in Rochelle salt (sodium potassium tartarate tetrahydrate;  $\text{NaKC}_4\text{H}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$ ) by Joseph Valasek [7]. Ferroelectrics are materials which possess a spontaneous electric polarization ( $P_s$ ) in the absence of an electric field and this polarization can be reversed by applying a suitable electric field ( $E$ ) [8]. An important feature of ferroelectric materials are hysteresis loop (abbreviated as P – E loop), which displays relationship between the polarization ( $P$ ) and applied electric field ( $E$ ).

**Figure 2.5** Venn diagram showing of dielectric materials [7]

The P – E hysteresis loop occur from the energy needed to switch the domain and polarization in the direction of the external field. As shown in figure 2.6, when an electric field is applied to a crystal with randomly oriented dipoles (or domains), they begin to line up with the field from points O to B, until the saturation polarization ( $P_s$ ) is reached at points C, and all of the dipoles are aligned. When the field is

removed, there is some remanent polarization ( $P_r$ ) at point D due to coupling between all of the dipoles, and the material is permanently polarized. When the electric field is applied in the opposite direction, the dipoles are reversed. A coercive field ( $E_c$ ) must be applied in order to remove the remanent polarization (point F), and create a random dipole orientation. As the reversed field is further increased, saturation occurs with the opposite polarization at point G. As the field continues to alternate, a hysteresis loop is formed. The area inside the loop is a function of the energy required to switch the direction of the polarization 180° [9].

**Figure 2.6** A typical ferroelectric hysteresis loop ((P – E) hysteresis loop) [10]

For ferroelectric materials, another important characteristic is the temperature of structural phase transition from the paraelectric phase to the ferroelectric phase which is called Curie temperature ( $T_c$ ). The temperature is above  $T_c$  the crystal does

not exhibit ferroelectricity. On the other hand, when the temperature falls below  $T_c$ , the crystal exhibits ferroelectricity. According to the Curie – Weiss law equation [10];

$$\frac{1}{\epsilon} = \frac{(T - T_0)}{C} \quad (2.5)$$

Where, C is the Curie – Weiss constant, T is the temperature,  $T_0$  is the Curie – Weiss temperature which is formula constant obtained by extrapolation and is less than  $T_c$ . While  $T_c$  is actual temperature when crystal structure changes.

### 2.2.2 Relaxor ferroelectrics

Relaxor ferroelectrics or relaxors are a class of ferroelectric materials that were first discovered in the 1950's by Smolenskii *et al.* [11]. The Relaxor ferroelectrics can be categorized into two structural families: the first is complex perovskites and the last is tungsten bronze system. For some examples of common relaxor ferroelectrics are  $\text{Pb}(\text{Mg}_{1/3}\text{Nb}_{2/3})\text{O}_3$ ,  $(\text{Pb}_{1-3x/2}\text{La}_x)(\text{Zr}_y\text{Ti}_{1-y})\text{O}_3$ ,  $\text{Pb}_{1-x}\text{Ba}_x\text{Nb}_2\text{O}_6$ , and  $\text{Pb}(\text{Zn}_{1/3}\text{Nb}_{2/3})\text{O}_3$ . These materials have high piezoelectric, dielectric, pyroelectric and electro-optic properties. Therefore, application of relaxor ferroelectric have been widely used in industry such as high permittivity capacitors, phase conjugate mirrors, piezoelectric sensors and actuators [12]. The hysteresis loop of relaxor this zero field polarization is significantly smaller owing to the fact that the the nanodomains being randomly distributed. Three qualitative features of the dielectric response of relaxors can be summarized as follows [13, 14]: the first, the peak at phase transition are characterized rounded and broad peaks in the temperature dependence of the dielectric permittivity. Secondly, the relaxors exhibit frequency dependent maximum dielectric permittivity, when the temperature of maximum relative permittivity ( $T_m$ ) increasing and maximum relative permittivity ( $\epsilon_{\text{max}}$ ) decreasing with increasing frequency and the last, the temperature of maximum relative permittivity is called  $T_m$ .

In order to further characterize the relaxor behavior, a modified Curie – Weiss law (is called quadratic Curie – Weiss) was used for description a broad relative permittivity and diffuseness of phase transition [15].

$$\frac{\varepsilon_{\max}}{\varepsilon} = 1 + \frac{(T - T_m)^\gamma}{\delta_\gamma^2} \quad (2.6)$$

Where,  $\varepsilon_{\max}$  is the maximum value of relative permittivity and  $T_m$  is the temperature of dielectric maximum. The  $\gamma$  value expresses the degree of dielectric relaxation in relaxor ferroelectric material which this value is in the range of  $1 \leq \gamma \leq 2$ . When  $\gamma$  value is equal 1, becomes the classic Curie Weiss law valid in the case of normal ferroelectric. The value of  $\delta_\gamma$  represents the degree of diffuseness for transition peaks. Both  $\delta_\gamma$  and  $\gamma$  were determined from the slope and intercept of  $\ln\left(\frac{1}{\varepsilon} - \frac{1}{\varepsilon_m}\right)$  versus  $\ln(T - T_m)$ .

### 2.3 Perovskite structure

Perovskites is an important class of piezoelectric materials. Perovskite is originally the name of the mineral calcium titanate ( $\text{CaTiO}_3$ ) [16]. An idea perovskite structure can be described as a simple cubic unit cell with a closed-packed face center cubic (FCC) structure. The perovskite structure is written as  $\text{ABO}_3$ , where A illustrate a cation with a larger ionic radius on the comers, and B show a cation with a smaller ionic radius in the body center or octahedral interstitial site and O is oxygen in the center of the faces [17], as shown in Figure 2.7. The A site is in 12-fold coordination, the B site is in 6-fold coordination, and the O site is 6-fold coordinated anions. There are many complex perovskites which can be describe with the formula  $(A', A'')^{\text{XII}}(B', B'')^{\text{VI}}\text{O}_3$  where XII and VI represent coordination number. In KNN,  $\text{K}^+$  or  $\text{Na}^+$  ions are situated at the corner of the unit cell (A – site),  $\text{Nb}^{5+}$  at body center positions (B – site).

Ideal perovskite structure is simple cubic lattice. The simple geometrical relationship between cations and anions which can be used to describe the stability of the perovskite structure proposed by Goldschmidt in early 1920 [19]. The stability of the perovskite structure is the tolerance factor which can be expressed as following equation [1]:

$$t = \frac{(R_A + R_O)}{\sqrt{2}(R_B + R_O)} \quad (2.7)$$

where  $t$  is tolerance factor.  $R_A$ ,  $R_B$  and  $R_O$  are the ionic radius of the large cation occupying the A – site, small cation occupying the B – site, and anion (oxygen) respectively. For ideal cubic symmetry, the tolerance factor is equal to 1. The stable perovskite structure, tolerance factor should be in the between range  $0.88 < t < 1.09$ . In general, the perovskite with  $t > 1$  has tetragonal symmetry and the perovskite with  $t < 1$  has rhombohedral or monoclinic symmetry [20].

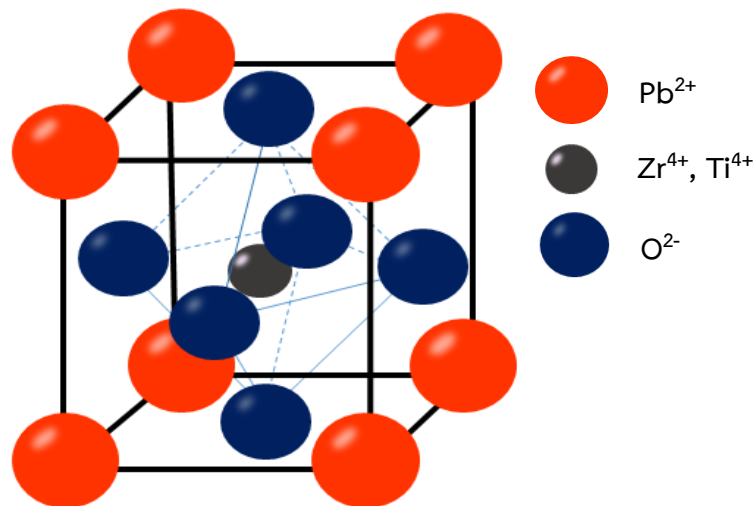

Figure 2.7  $ABO_3$  perovskite type unit cell (Modified from [18])

## 2.4 Lead-based piezoelectric materials

The commercially most important piezoelectric material lead zirconate titanate ( $PbZr_{1-x}Ti_xO_3$ ; PZT) was developed since in 1950's [21]. Lead zirconate titanate is solid solution of lead zirconate ( $PbZrO_3$ ) and lead titanate ( $PbTiO_3$ ) which it is a perfect sample of polycrystalline ceramics. Currently, the lead zirconate titanate is the most widely used piezoelectric material for numerous electronic devices utilizing actuators, sensors and transducers [22]. Above the Curie temperature ( $T_c$ ), lead zirconate titanate obtains the cubic perovskite structure where the A – site is  $Pb^{2+}$  (Large cation) on the comers, B – site are  $Zr^{4+}$  and  $Ti^{4+}$  in the body center and O is oxygen in the face centers [23], as shown in figure 2.8.

**Figure 2.8** Perovskite structure of lead zirconate titanate (Modified from [24])

The form of the crystalline structure exhibited by lead zirconate titanate is dependent on the percentage concentration of metal oxides. The phase diagram of the lead zirconate titanate system as a function of temperature and chemical composition is shown in figure 2.9. The morphotropic phase boundary (MPB) defines the composition at which there is an abrupt structure change, the composition being almost independent of temperature. Moreover, the nearly vertical line separates the ferroelectric phase region of tetragonal phase on the Ti rich side ( $F_T$ ) and rhombohedral phase on the Zr rich side ( $F_R$ ). The  $T_c$  line is the boundary between the cubic paraelectric phase ( $P_c$ ) and the ferroelectric phase ( $F$ ). For below  $T_c$  line, the substitution of  $Zr^{4+}$  for  $Ti^{4+}$  in  $PbTiO_3$  changes the rhombohedral distortion in favour of the tetragonal symmetry in the PZT perovskite structure. The nearly vertical morphotropic phase boundary (MPB) at 52:48 for Zr/Ti cation ratio, had coexistence phase of a tetragonal and rhombohedral phase. This compositions in the morphotropic phase boundary region are commercially interesting because they have shown high dielectric permittivity and piezoelectric electromechanical coupling factors, as shown in figure 2.10 [26]. The enhanced dielectric and piezoelectric properties of the commercial composition is generally associated with a large ionic displacement upon field application due to the rotation of the polar axis. Furthermore, other system of lead base systems exhibit excellent piezoelectric and

dielectric properties such as  $\text{Pb}(\text{Mg}_{1/3}\text{Nb}_{2/3})\text{O}_3\text{-PbTiO}_3$  [27],  $\text{Pb}(\text{Zn}_{1/3}\text{Nb}_{2/3})\text{O}_3\text{-PbTiO}_3$  [28, 29] and  $\text{Pb}(\text{Zr}_{1/2}\text{Ti}_{1/2})\text{O}_3 - \text{Pb}(\text{Zn}_{1/3}\text{Nb}_{1/3})\text{O}_3$  [30].

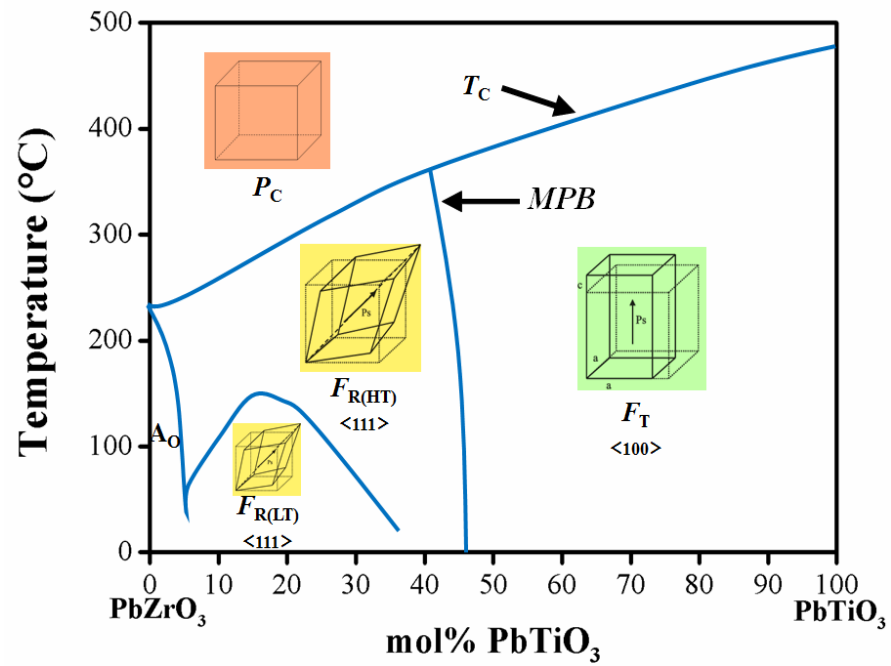

Figure 2.9 Lead zirconate titanate phase diagram (Modified from [25])

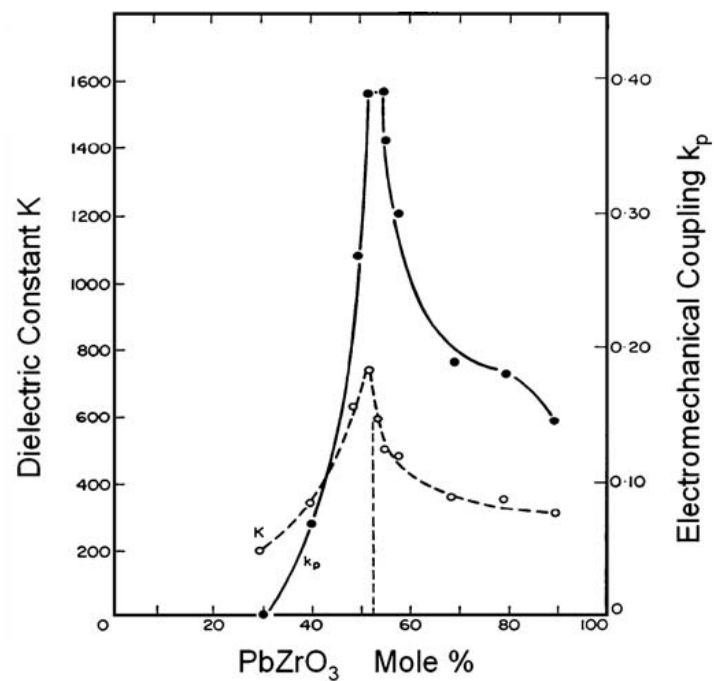

Figure 2.10 Enhanced dielectric and piezoelectric properties in lead zirconate titanate [26]

However, the lead base materials contain lead which it is not environmental friendly and dangerous to human because toxicity of lead oxide is volatile during processing. Therefore, legislation of European Union such as Waste from Electrical and Electronic Equipment (WEEE) and Restriction of Hazardous Substances (RoHS) directives and End-of Life Vehicles (ELV) restrict the use of six hazardous substances including lead in electronic equipment. To prevent generation of new waste, and reuse or recycle electrical waste and electronic equipment [31, 32, 33]. Therefore, lead free friendly piezoelectric ceramics have been received considerable attentions to replace lead-based piezoelectric materials.

## 2.5 Lead-free piezoelectric materials

Current research is mostly focus on lead free piezoelectric materials Among the lead free materials, Potassium sodium niobate with the chemical formula  $(K, Na)NbO_3$  (abbreviated as KNN), is a solid solution of ferroelectric  $KNbO_3$  and the antiferroelectric  $NaNbO_3$ . The phase diagram of  $KNbO_3$ – $NaNbO_3$  is exhibited in Figure 2.11. The MPB at near the 50-50 ratio of  $KNbO_3$ – $NaNbO_3$  separates two tetragonal phases at high temperatures and two orthorhombic phases at room temperature, with different tilting of the oxygen octahedral [5, 34]. Moreover,  $(K_{0.5}Na_{0.5})NbO_3$ , is a good candidate because it has a fairly high Curie temperature ( $T_c$ ) about 420°C, which is high temperature application. Nevertheless, it's difficult to obtain fully dense  $(K_{0.5}Na_{0.5})NbO_3$  ceramics by ordinary sintering.

In addition to, the bismuth-based perovskite lead-free materials is bismuth potassium titanate,  $(Bi_{0.5}K_{0.5})TiO_3$  (abbreviated as BKT) and bismuth sodium titanate  $(Bi_{0.5}Na_{0.5})TiO_3$  (abbreviated as BNT). The  $(Bi_{0.5}K_{0.5})TiO_3$  is a typical ferroelectric material with tetragonal structure at room temperature and has a higher Curie temperature about 380°C [35]. In 1961, Smolenskii et al. discovered  $(Bi_{0.5}Na_{0.5})TiO_3$  [36]. At room temperature, it shows large remnant polarization ( $P_r$ ) 38  $\mu C/cm^2$  and coercive field ( $E_c$ ) 73 kV/cm.  $(Bi_{0.5}Na_{0.5})TiO_3$  has rhombohedral structure at room temperature with a high Curie temperature about 320°C [37]. However the piezoelectric properties are not good enough due to its large coercive field and relatively high conductivity, thus pure BNT is hard to pole. Some electrical properties of pure  $(Bi_{0.5}K_{0.5})TiO_3$  [38] and  $(Bi_{0.5}Na_{0.5})TiO_3$  [5] is shown in table 2.1

Figure 2.11 Phase diagram of KNbO<sub>3</sub>-NaNbO<sub>3</sub> [5]

Table 2.1 Some electrical properties of pure (Bi<sub>0.5</sub>K<sub>0.5</sub>)TiO<sub>3</sub> and (Bi<sub>0.5</sub>Na<sub>0.5</sub>)TiO<sub>3</sub>

	$\epsilon_r$	$\tan \delta$	$k_{33}$	$d_{33}$ (pC/N)	$P_r$ ( $\mu\text{C}/\text{cm}^2$ )	$E_c$ (MV/m)
(Bi <sub>0.5</sub> K <sub>0.5</sub> )TiO <sub>3</sub>	300	1.1	0.4	70.0	38.0	7.30
(Bi <sub>0.5</sub> Na <sub>0.5</sub> )TiO <sub>3</sub>	517	7.1	0.28	69.8	22.2	5.25

Therefore, this thesis work focuses on developing ferroelectric and piezoelectric material that are lead free materials of barium titanate base

### 2.5.1 Barium titanate (BaTiO<sub>3</sub>, BT)

In 1945, Wol and Goldman discovered BaTiO<sub>3</sub> with the chemical formula BaTiO<sub>3</sub> (abbreviated as BT) [39]. BaTiO<sub>3</sub> was the first ferroelectric material and later on the first piezoelectric ceramic. It is widely used a dielectric material for ceramic capacitors, and as a piezoelectric material for microphones and other transducers [4].

Furthermore, It possesses the perovskite crystallographic structure where the A – site is  $\text{Ba}^{2+}$  on the comers, B – site is  $\text{Ti}^{4+}$  in the body center and O is  $\text{O}^{2-}$  in the face centers. These four crystal structures of  $\text{BaTiO}_3$  are rhombohedral, orthorhombic, tetragonal and cubic.  $\text{BaTiO}_3$  has various phase transition as a function of the temperature. At the Curie temperature about  $130^\circ\text{C}$  change from tetragonal (ferroelectric) to cubic (paraelectric) phase. Above  $130^\circ\text{C}$ , it has a cubic structure which it is centro – symmetric and possesses no spontaneous dipole. As the low Curie temperature, the structure is slightly distorted to the tetragonal phase with a dipole moment with the [001] direction. The phase transition at temperature  $-80^\circ\text{C}$  change from rhombohedral to orthorhombic phase, whereas a transition from orthorhombic to tetragonal phase occur temperature near  $0^\circ\text{C}$ . The phase transition of  $\text{BaTiO}_3$  is illustrated in figure 2.12 [1]. Moreover, the phase transition of  $\text{BaTiO}_3$  are corresponded to change in values of the lattice parameter, Relative permittivity and spontaneous polarization, as shown in figure 2.13 [1], 2.14 [40] and 2.15 [1] respectively.

**Figure 2.12** Unit cell distortions of  $\text{BaTiO}_3$  structure [1]

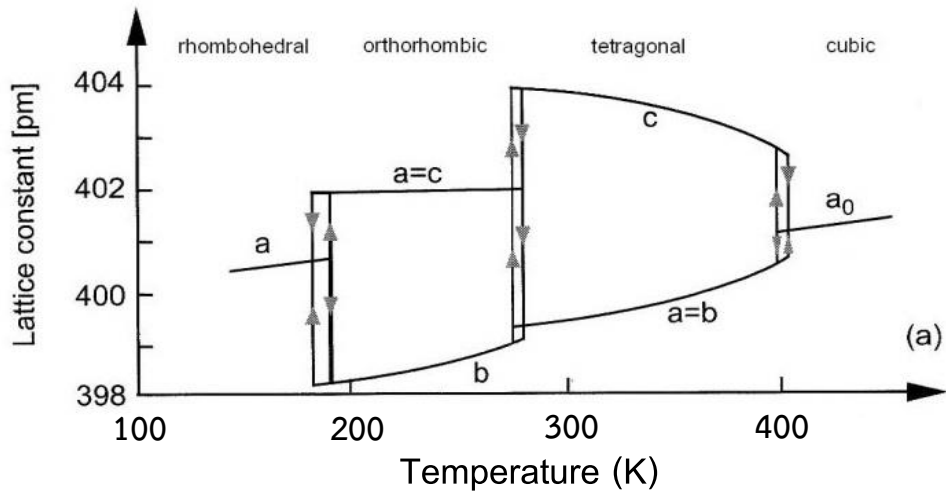

Figure 2.13 Lattice parameters versus temperature [1]

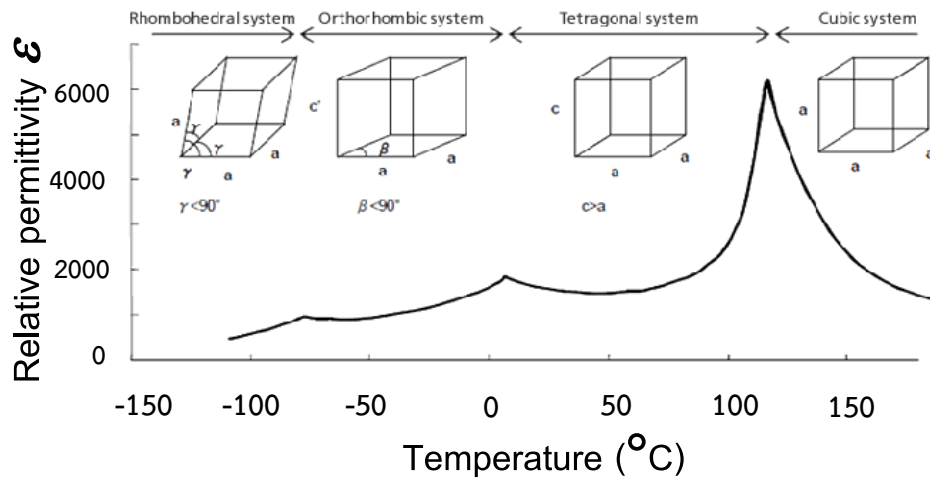

Figure 2.14 Relative permittivity versus temperature [40]

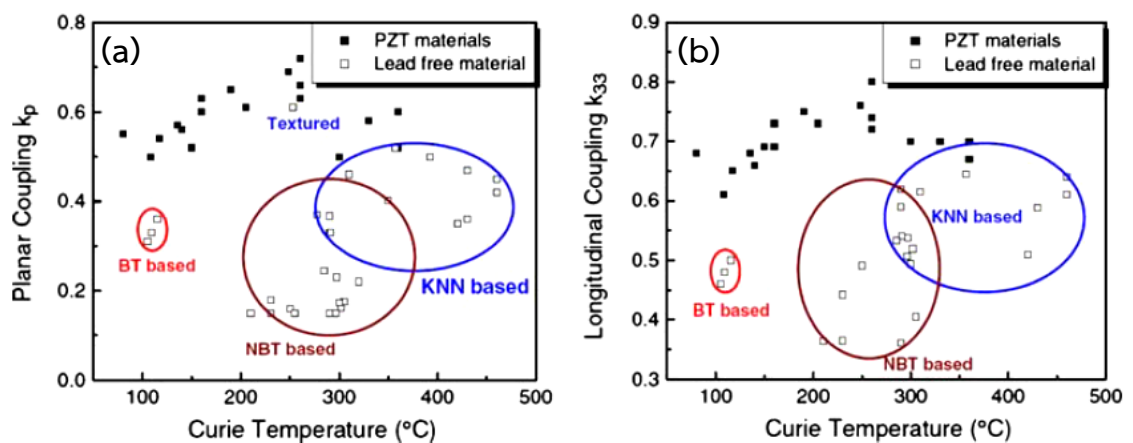

Figure 2.15 Spontaneous polarization versus temperature [1]

The electrical properties of BaTiO<sub>3</sub> ceramics such as dielectric ferroelectric and piezoelectric properties is shown in Table 2.2 [41]. It is seen that BaTiO<sub>3</sub> has good ferroelectric and piezoelectric properties. Nevertheless, the comparison electrical properties of pure BaTiO<sub>3</sub> and PZT material is also quite evident that electrical properties of PZT material is higher than pure BaTiO<sub>3</sub> material, as show in figure 2.16 and 2.17 [41].

**Table 2.2** Some parameter of electrical properties for Barium titanate ceramics [41]

Electrical parameter	Value
Curie Temperature, $T_C$ (°C)	130
Relative permittivity, $\epsilon_r$ (at 1 kHz)	1700
Dielectric loss, $\tan\delta$ (at 1 kHz)	0.01
Remnant polarization, $P_r$ ( $\mu\text{C}/\text{cm}^2$ )	13.3
Piezoelectric $d_{33}$ coefficient (pC/N)	190
Piezoelectric $d_{31}$ coefficient (pC/N)	-78
Electromechanical coupling coefficient, $k_{33}$	0.49

**Figure 2.16** (a) Planar Coupling;  $k_p$  and (b) Longitudinal Coupling;  $k_{33}$  versus Curie temperature [41]

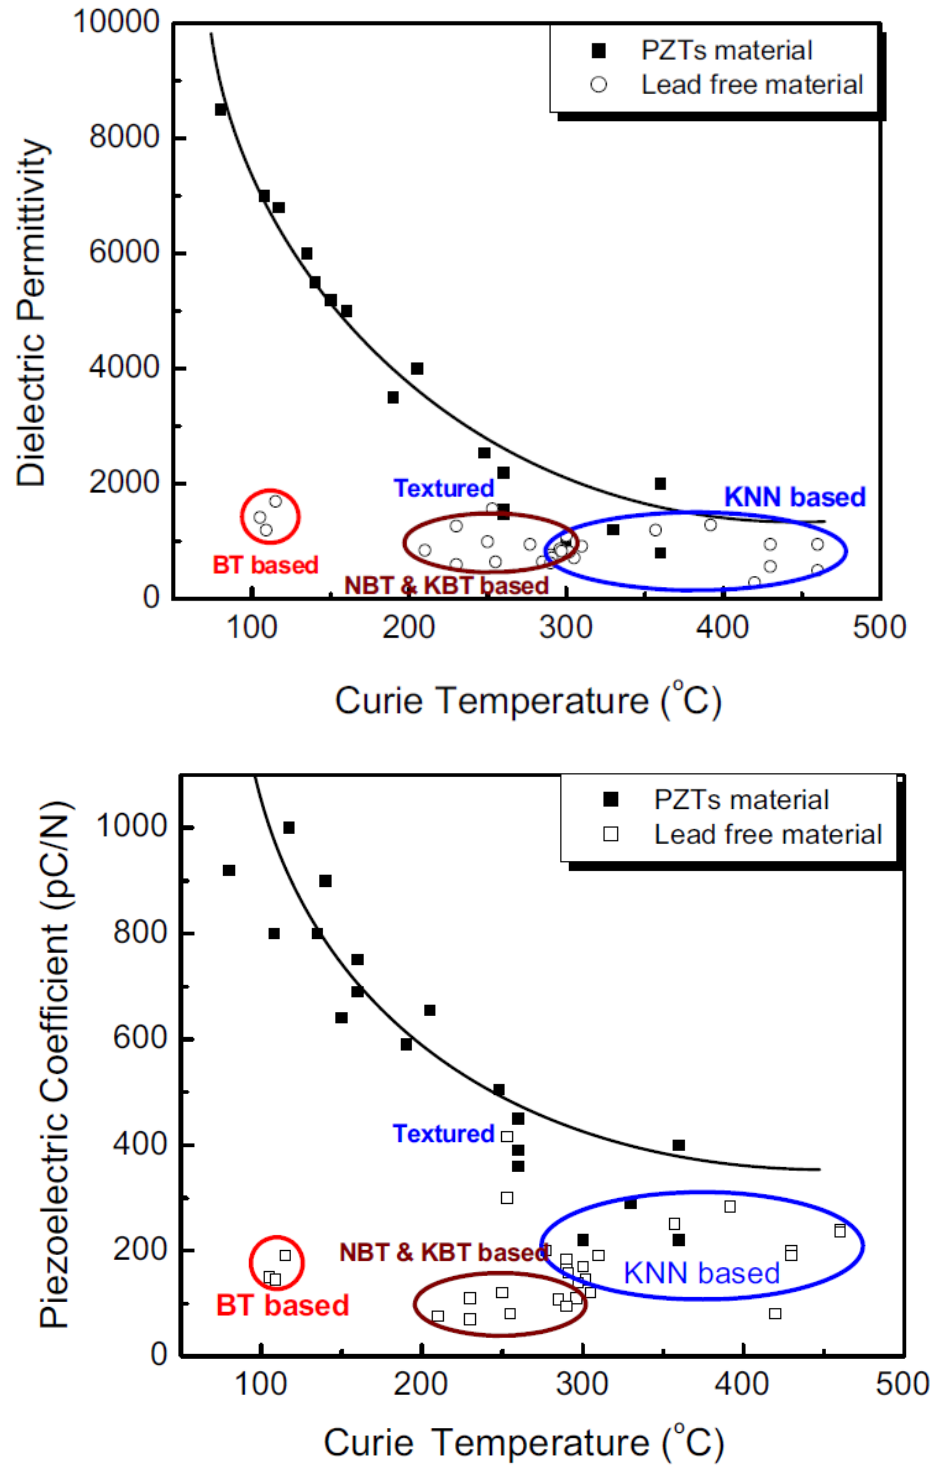

Figure 2.17 Dielectric permittivity and Piezoelectric Coefficient versus Curie temperature [41]

Therefore, the attention is improve electrical properties of BaTiO<sub>3</sub> material with comparable to electrical properties of PZT material. Many paper of BT-base have been modified by doping with either A or/and B site substitutions. In addition to, research is focus on morphotropic phase boundary (MPB) or polymorphic phase transition (PPT) due to it excellent electrical properties.

### 2.5.1.1 Binary system of BaTiO<sub>3</sub> material

In a few decades, Guo *et al.* studied BaTiO<sub>3</sub>-K<sub>1/2</sub>Na<sub>1/2</sub>NbO<sub>3</sub> ceramics. They found that the phase transition at  $x = 0.02$  and  $0.06$  of BaTiO<sub>3</sub> changed tetragonal to cubic symmetry and orthorhombic to tetragonal symmetry, respectively. For composition  $x = 0.02$  exhibited enhanced piezoelectric and ferroelectric properties including  $P_r \sim 7.5 \mu\text{C}/\text{cm}^2$ ,  $E_C \sim 12 \text{ kV}/\text{cm}$ ,  $d_{33} \sim 104 \text{ pC}/\text{N}$ ,  $k_p \sim 0.29$  and  $T_C \sim 358^\circ\text{C}$  [42].

Meanwhile many researchers studied the binary system of BaTiO<sub>3</sub>-Bi<sub>0.5</sub>Na<sub>0.5</sub>TiO<sub>3</sub> [43, 44]. Takenaka *et al.* studied BaTiO<sub>3</sub>-Bi<sub>0.5</sub>Na<sub>0.5</sub>TiO<sub>3</sub> system. Researchers found a morphotropic phase boundary between rhombohedral and tetragonal phases at 6 mol% of BT as illustrated in figure 2.18. These MPB had excellent electrical properties such as  $T_C \sim 288^\circ\text{C}$ ,  $\epsilon_{33}^T / \epsilon_0 \sim 580$ ,  $\tan\delta \sim 1.3\%$ ,  $d_{33} \sim 125 \text{ pC}/\text{N}$ , and  $k_{33} \sim 55.0\%$  [43]. In 2013 Rawat *et al.* studied BaTiO<sub>3</sub>-Bi<sub>0.5</sub>Na<sub>0.5</sub>TiO<sub>3</sub> system. They reported that the  $P_r$  and  $E_C$  increasing with increasing BNT content and the  $T_C \sim 155^\circ\text{C}$  at 10 mol% of BNT addition [45]. Furthermore, Wada *et al.* studied lead free BaTiO<sub>3</sub> and Bi(Mg<sub>0.5</sub>Ti<sub>0.5</sub>)O<sub>3</sub> (BT-BMT) ceramic. They found that the highest  $T_C \sim 360^\circ\text{C}$  at 0.05 mol% of BMT [46].

In 2005 Xusheng *et al.* prepared (1-x)BaTiO<sub>3</sub>-xCaTiO<sub>3</sub> system via conventional solid-state reaction. They reported that the composition  $x = 0.23$  exhibited high electrostriction strain  $\sim 0.22\%$  due to it had two of tetragonal Ba<sub>0.8</sub>Ca<sub>0.2</sub>TiO<sub>3</sub> and orthorhombic Ba<sub>0.07</sub>Ca<sub>0.93</sub>TiO<sub>3</sub> solid solution [47]. After that, Dong *et al.* studied (1-x)BaTiO<sub>3</sub>-xBaZrO<sub>3</sub> ceramic. They found that the diffused phase transition behavior was enhanced with increasing BZ content. At composition  $x = 0.06$  had high piezoelectric and dielectric properties ( $d_{33} = 420 \text{ pC}/\text{N}$ ,  $d_{31} = -138 \text{ pC}/\text{N}$ ,  $k_p = 0.49$  and  $\epsilon_r = 2500$ ) [48]. At the same time, Yonggang *et al.* studied the effect of BaSnO<sub>3</sub> observed large piezoelectricity and dielectric permittivity in BaTiO<sub>3</sub>-xBaSnO<sub>3</sub> systems. They found that four phase coexistence of Cubic-Tetragonal-Orthorhombic-Rhombohedral

phase at  $x = 0.11$ , exhibited large piezoelectricity and dielectric permittivity ( $\epsilon_r \sim 75,000$  and  $d_{33} \sim 697$  pC/N), as shown in figure 2.19 [49].

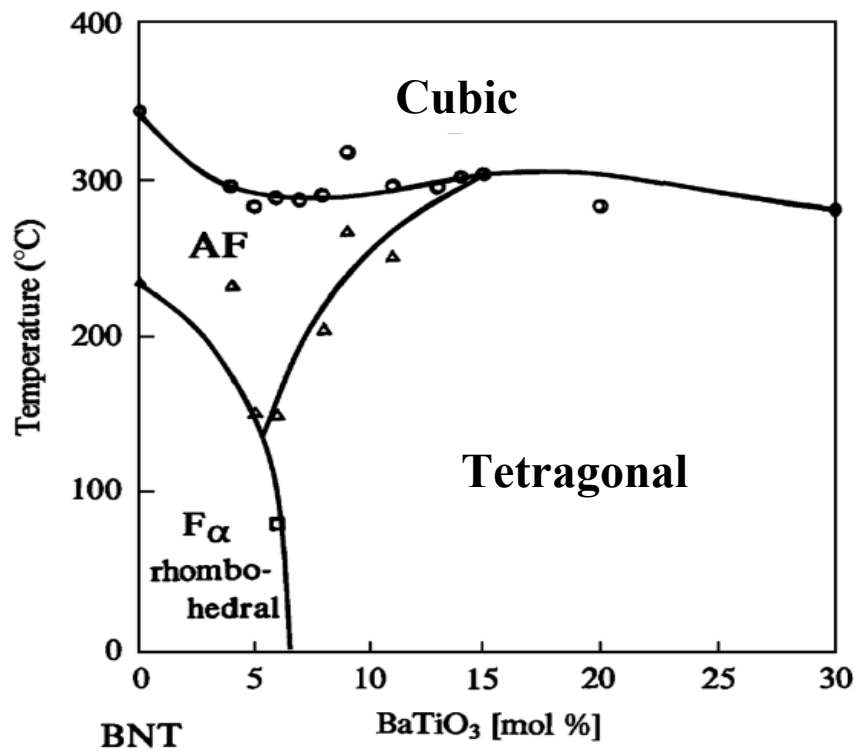

Figure 2.18 Temperature-composition phase diagram of BT-BNT [13]

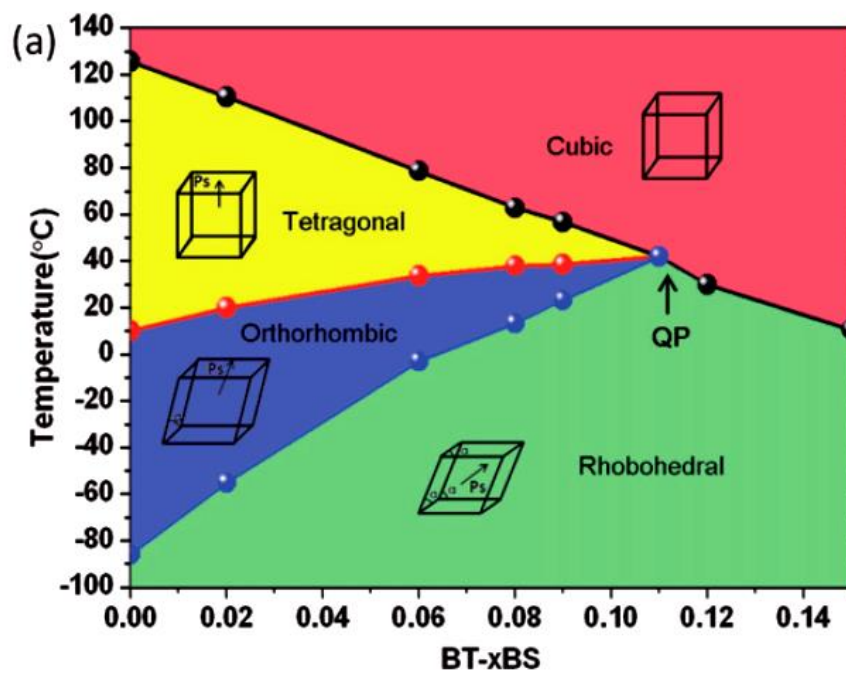

Figure 2.19 Temperature-composition phase diagram of BaTiO<sub>3</sub>-xBaSnO<sub>3</sub> [49]

### 2.5.1.2 Ternary system of BaTiO<sub>3</sub> material

Meanwhile, many research focus on ternary system of BaTiO<sub>3</sub> material. In 2008, Zhang *et al.* studied lead free  $x\text{BT}-(1-x-y)\text{BNT}-y\text{KNN}$  system. They found that lead free 6BT–92BNT–2KNN ceramics exhibited the giant strain about 0.45% under both a unipolar and bipolar electric field at 80 kV/mm, as shown in figure 2.20 [50]. Afterward, Rahman *et al.* prepared lead free  $6.5\text{BaTiO}_3-(93.5-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{BaZrO}_3$  (BNBT–xBZ) by conventional solid-state reaction method. They reported that BNBT–0.03BZ ceramic had high  $d_{33}^* \sim 542$  pm/V and strain  $\sim 0.38\%$  at an applied field of 7 kV/mm [51].

Moreover, Trelcat *et al.* studied lead free  $x\text{BaTiO}_3-y\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-z\text{Bi}_{0.5}\text{K}_{0.5}\text{TiO}_3$  system ( $x\text{BT}-y\text{BNT}-z\text{BKT}$ ). Researcher reported that the 3.5BT–86.5BNT–10BKT ceramic exhibited high piezoelectric constant and electromechanical coupling factors ( $d_{33} \sim 133$  pC/N,  $k_p \sim 0.26$  and  $k_t \sim 0.26$ ) [52].

Figure 2.20 The relative plot of unipolar strain (%) of  $x\text{BT}-(1-x-y)\text{BNT}-y\text{KNN}$  ceramic as a function of electric field (kV/cm) [50]

In recent years, Li *et al.* synthesized  $(\text{Ba}_{1-x}\text{Ca}_x)(\text{Ti}_{0.95}\text{Zr}_{0.05})\text{O}_3$  system using a solid-state reaction technique. They reported that the PPT from orthorhombic to

tetragonal phase at  $x = 0.08$  showed high piezoelectric properties ( $d_{33} \sim 365$  pC/N and  $k_p \sim 48.5\%$ ) [53]. In 2010, Sutapun *et al.* studied  $0.87\text{BaTiO}_3-(0.13-x)\text{BaZrO}_3-x\text{CaTiO}_3$  ceramic. They found that the multiphase coexistence of the rhombohedral and tetragonal phase at  $x = 0.06$  (figure 2.21) exhibited high  $d_{33}^* \sim 1280$  pm/V at electric field 10 kV/cm and strain  $\sim 0.23\%$  at electric field 40 kV/cm [54].

Recently, Zhu *et al.* synthesized  $(\text{Ba}_{1-x}\text{Ca}_x)(\text{Ti}_{0.92}\text{Sn}_{0.08})\text{O}_3$  [55] and  $(\text{Ba,Ca})(\text{Ti}_{1-x}\text{Sn}_x)\text{O}_3$  [56] ceramics. For  $(\text{Ba}_{1-x}\text{Ca}_x)(\text{Ti}_{0.92}\text{Sn}_{0.08})\text{O}_3$  ceramics, they found that the PPT from orthorhombic phase to tetragonal phase at  $x = 0.05$  presented high dielectric and piezoelectric properties ( $\epsilon_r \sim 23000$ ,  $k_p \sim 47.7\%$ ,  $d_{33} \sim 568$  pC/N and  $d_{33}^* \sim 1013$  pm/v) [55]. Another  $(\text{Ba,Ca})(\text{Ti}_{1-x}\text{Sn}_x)\text{O}_3$  system, they reported that the multiphase coexistence of R-PC-O at  $x = 0.11$  (figure 2.22) exhibited ultrahigh  $d_{33} \sim 670$  pC/N and electrostrain 0.061% [56].

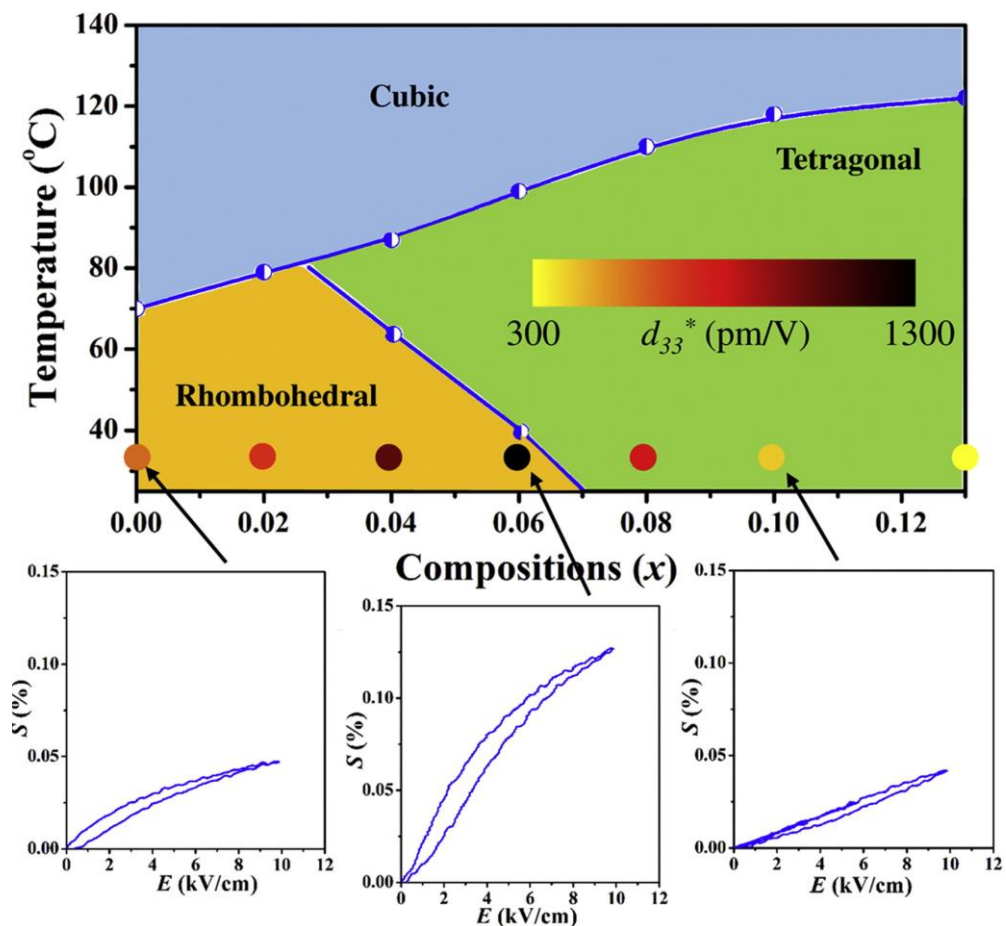

Figure 2.21 Composition-temperature ferroelectric phase diagram of BT-BZ-xCT ceramics [54]

Hao-Ran Li *et al.* studied lead free  $(\text{Ba}_{1-x}\text{Sr}_x)(\text{Zr}_{0.05}\text{Ti}_{0.95})\text{O}_3$  or BSTZ ceramic. They found that BSTZ with  $x = 0.11$  showed enhance piezoelectric properties ( $d_{33} \sim \text{pC/N}$  and  $k_p \sim 0.38$ ) [57]. In 2009, Yanxia Li *et al.* prepared  $\text{Ba}_{1-x}\text{Sr}_x\text{Ti}_{0.94}\text{Sn}_{0.06}\text{O}_3$  (BSTS) ceramics by solid-state reaction method. Researchers reported that the BSTS at  $x = 0.02$  exhibited maximum tunability of 63.5% at applied electric field of 6 kV/cm [58].

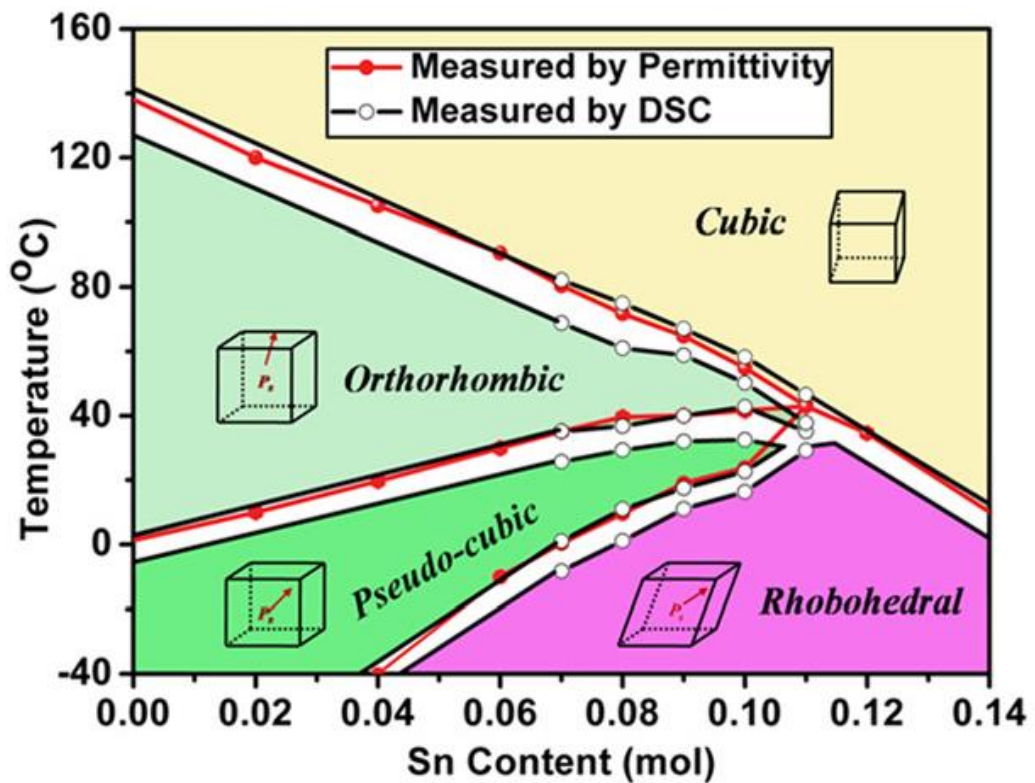

Figure 2.22 Temperature-composition phase diagram of  $(\text{Ba,Ca})(\text{Ti}_{1-x}\text{Sn}_x)\text{O}_3$  [56]

Jiagang Wu *et al.* prepared BT-base ceramic by combining  $(1-x)\text{Ba}_{0.98}\text{Ca}_{0.02}\text{Ti}_{0.94}\text{Sn}_{0.06}\text{O}_3-x\text{Ba}_{0.85}\text{Ca}_{0.15}\text{Ti}_{0.90}\text{Zr}_{0.10}\text{O}_3$   $((1-x)\text{BCTS}-x\text{BCTZ})$  system. The phase boundary coexistence of orthorhombic and tetragonal phase was observed at around 4 mol% BCTZ which show good dielectric and piezoelectric properties ( $\epsilon_r \sim 5500$ ,  $\tan\delta \sim 0.3\%$  and  $d_{33} \sim 407 \text{ pC/N}$ ) [59]. In 2009, Liu and Ren studied lead free  $\text{Ba}(\text{Ti}_{0.8}\text{Zr}_{0.2})\text{O}_3-(\text{Ba}_{0.7}\text{Ca}_{0.3})\text{TiO}_3$  (BZT–BCT) system which it showed high  $d_{33} \sim 620 \text{ pC/N}$  and  $d_{33}^* \sim 1140 \text{ pm/V}$  at 50BZT–50BCT composition. The MPB of BZT–BCT ceramic exhibited tricritical triple point of a cubic paraelectric phase, ferroelectric rhombohedral, and tetragonal phases, which leads to a nearly vanishing polarization

between [001] tetragonal and [111] rhombohedral states, as illustrated in figure 2.23 [60].

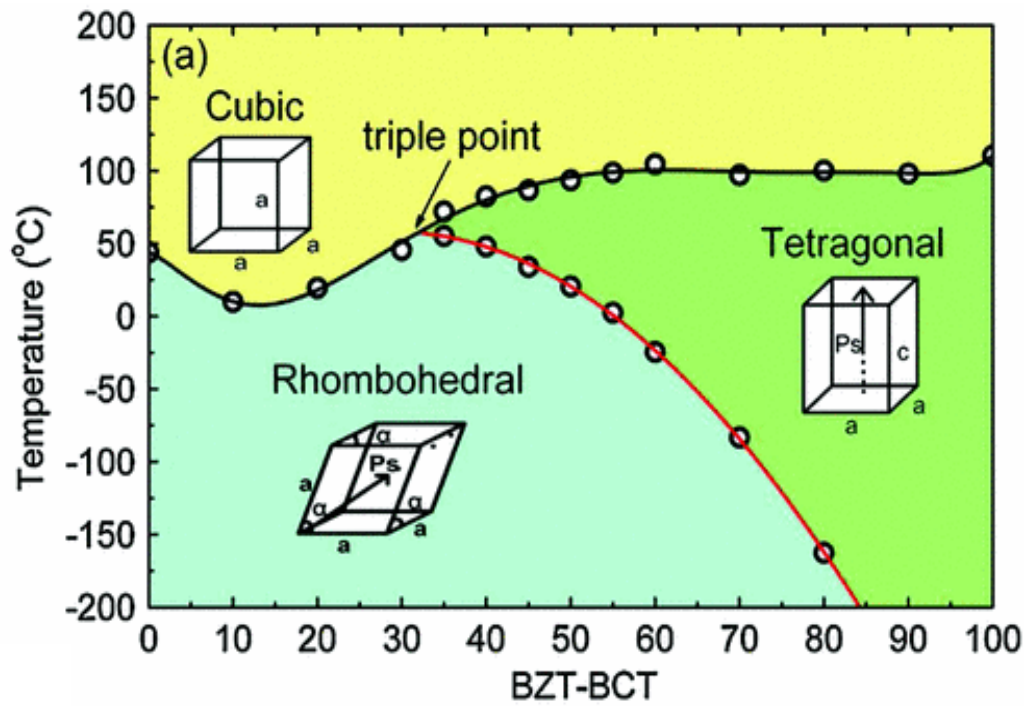

Figure 2.23 Phase diagram of  $\text{Ba}(\text{Ti}_{0.8}\text{Zr}_{0.2})\text{O}_3-(\text{Ba}_{0.7}\text{Ca}_{0.3})\text{TiO}_3$  ceramic [60]

## CHAPTER 3

### EXPERIMENTAL PROCEDURES

In this section explains experimental procedures used for the preparation powders ceramic processing and characterization of ternary barium titanate base ceramics. The characterizations of BT-based ceramics were describes physical and electrical properties.

#### 3.1 Powder preparation

In this studies, BT-based powders of  $(0.975-y)\text{BaTiO}_3-0.025\text{SrTiO}_3-y\text{BaSnO}_3$  and  $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  systems were prepared using a solid-state by mixed carbonate and oxide method. The chemical purity and supplier of raw materials were used for preparations BT-based systems are listed in Table 3.1. For the raw material of  $(0.975-y)\text{BaTiO}_3-0.025\text{SrTiO}_3-y\text{BaSnO}_3$  system were mixed by vibratory milled and  $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  system were mixed by rotational ball milled. The starting materials were treated and dried in oven at  $100^\circ\text{C}$  before use. The oxide and carbonate powder were weighted according to the molar ratios of unit formula mixed and milled with yttrium-stabilized zirconia media in ethyl alcohol (ethanol). After that the mixture was dried in oven at  $100^\circ\text{C}$  for 24 hours and calcined in closed alumina crucibles for an optimized temperature range for each system. Then the calcined powders were ground and sieved. The procedure of all powder preparations in this studied is shown in figure 3.1.

**Table 3.1** Specifications of starting precursors used in this study

Chemical	Purity (%)	Suppliers
Barium carbonate ( $\text{BaCO}_3$ )	99.9%	Inframal Advance Materials
Bismuth oxide ( $\text{Bi}_2\text{O}_3$ )	99.9%	Sigma-Aldrich
Sodium carbonate ( $\text{Na}_2\text{CO}_3$ )	99.8%	Riedel-de Hean
Titanium dioxide $\text{TiO}_2$	99.9%	Sigma-Aldrich
Magnesium oxide ( $\text{MgO}$ )	99%	Fluka
Tin oxide ( $\text{SnO}_2$ )	99.9%	Sigma-Aldrich
Strontium carbonate ( $\text{SrCO}_3$ )		Inframal Advance Materials

### 3.1.1 Powder preparation of $(0.975-y)\text{BaTiO}_3-0.025\text{SrTiO}_3-y\text{BaSnO}_3$

The composition series of  $(0.975-y)\text{BaTiO}_3-0.025\text{SrTiO}_3-y\text{BaSnO}_3$  (abbreviated as BT-ST-yBS), where  $y = 0.00, 0.02, 0.04, 0.06, 0.08$  and  $0.10$  ceramics were fabricated via solid-state reaction technique. The metals oxide and carbonate powder of  $\text{BaCO}_3$ ,  $\text{SrCO}_3$ ,  $\text{TiO}_2$  and  $\text{SnO}_2$  were used as starting materials. In the mixing process, the stoichiometric amount of raw materials were weights by following the equation (3.1).

These powders were mixed in ethanol with yttrium-stabilized zirconia and then vibro-milling for 6 hours. The mixture were dried and calcined in alumina crucible at  $1200^\circ\text{C}$  for 4 hours with heating / cooling rate  $5^\circ\text{C}/\text{min}$ . The calcined powder were ground and sieved. The procedure of BT-ST-yBS powder preparations in this studied is showed in Figure 3.1.

### 3.1.2 Powder preparation of $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$

Lead free  $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  (abbreviated as BT-BNT-xBMT) ceramics, where  $x = 0.00, 0.02, 0.04, 0.06, 0.08, 0.10$ , were synthesized by the solid state reaction, as shown figure 3.2.  $\text{Bi}_2\text{O}_3$ ,  $\text{BaCO}_3$ ,  $\text{Na}_2\text{CO}_3$ ,  $\text{TiO}_2$  and  $\text{MgO}$  powders were used raw materials. First, stoichiometric amounts of raw materials were weighted by following the equation (3.2)

The raw materials were mixed and ball-milled with yttrium-stabilized zirconia in ethanol media for 18 hours. After drying the mixture for 24 hours in an oven and the mixed powder was calcined at  $900^\circ\text{C}$  for 4 hours with heating/cooling rate  $10^\circ\text{C}/\text{min}$ . Finally procedure of powder preparation, the calcined powder were ground and sieved.

**Figure 3.1** The powder preparation procedure of BT-ST-yBS

Figure 3.2 The powder preparation procedure of BT-BNT-xBMT

## 3.2 Ceramic processing

### 3.2.1 $(0.975-y)\text{BaTiO}_3-0.025\text{SrTiO}_3-y\text{BaSnO}_3$ ceramics

All BT–ST–yBS powder were weighted about 0.8 g. These powder were mixed with 5% polyvinyl alcohol (PVA) binder and pressed into green pellet of 11 mm diameter by uniaxial pressing. Then the binder inside the discs can be burnt out at 500°C and dwell time of 2 hours with heating rate 2°C/min. After that the samples were sintered 1375°C for 4 hours with heating/cooling rate 5°C/min which the disks were placed on an alumina plate. The samples deal is shown in figure 3.3.

**Figure 3.3** Arrangement of ceramics for the sintering process of BT–ST–yBS system

### 3.2.2 $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$ ceramics

The calcined powder of BT–BNT–xBMT systems were weighted about 1.2 g. and mixed continuously with 5% polyvinyl alcohol (PVA) as a binder to obtain homogeneous mixture. These powder were pressed into disks with 15 mm diameter by cold uniaxial pressing. Then the green pellet were placed on the alumina powder-bed inside alumina crucible which had a layer of alumina and  $\text{BaTiO}_3$  powder, as shown in figure 3.4. After that the PVA binder inside the sample can be burnt out at around 500°C and holding for 2 hours with slowly heating rate 2°C/min. After the PVA burnout process, the disks were sintered 1150–1250°C for 4 hours with heating/cooling rate 5°C/min.

Figure 3.4 Arrangement of ceramics for the sintering process of BT–BNT–xBMT system

### 3.3 Characterization of ceramics

#### 3.3.1 Physical properties and structure determination

##### 3.3.1.1 Density measurement [1]

The density of sintered pellet is an index of its quality which is dependent on impurities and pores. It was determined using a water immersion technique at room temperature based on the Archimedes' principle. The density of each sample could be calculated (Equation 3.3)

$$\rho = \frac{W_d}{W_0 - W_i} \times \rho_{water} \quad (3.3)$$

Where,  $W_d$  = dry weight,  $W_i$  = ceramic weight in the water and  $W_0$  = the weight of ceramic after issuing from water.

Figure 3.5 Laboratory weights scale (Mittler Toledo)

### 3.3.1.2 X – ray diffraction analysis [2]

After sintering of green pallet, the crystal structure and phase transition of all ceramics was carried out X-ray diffraction technique. The scattering of X-ray is related to the interaction between X-ray and crystal lattice of the materials by the X-ray scattered from different lattices interfere with each other and produces a diffraction pattern upon the change of incident angle of the X-ray beam. The incident rays interact with the samples and produces constructive interference when conditions satisfy Bragg's law

$$n\lambda = 2d\sin\theta \quad (3.4)$$

Where,  $d$  = perpendicular distance between lattice planes of miller indices,  $\lambda$  = wavelength of the incident,  $\theta$  = glancing angle,  $n$  = an integer- 1, 2, 3... etc

Figure 3.6 SmartLab X-ray diffractometer

In this studies, The X-ray diffraction results were obtained a SmartLab X-ray diffractometer (Figure 3.6). The source of X-ray used Cu-K $\alpha$  radiation with  $\lambda = 1.5418 \text{ \AA}$ . The Data of X-ray diffraction were collected in the  $2\theta$  scan range of  $20 - 80^\circ$ , with a step size of  $0.02^\circ$  at a scanning rate of  $1.2^\circ$  per minute. The phases were determined by comparing the major peaks to the values listed on the Joint Committee on Powder Diffraction Standards (JCPDS) and the peaks of X-ray diffraction pattern were calculated lattice parameter.

### 3.3.1.3 Scanning Electron Microscopy (SEM) [3]

Microstructure of the ceramic can be examined using scanning electron microscopy. In this studies, the surface morphology of ceramics was observed using scanning electron microscope (EVO@MA10) (Figure 3.7) by attaching the ceramic on stainless steel stubs using carbon adhesive tape. After that, the top surface of the sample was coated by gold layer. The calculation of average grain size of the ceramics were using linear intercept method.

Figure 3.7 Scanning electron microscope (EVO@MA10)

### 3.3.1.4 Raman spectroscopy [4]

Raman spectroscopy is a spectroscopic technique based on inelastic scattering of monochromatic light, usually from a laser source. The ceramics, Raman spectroscopy is used to investigate the vibration modes and sensitivity of local structure in inorganic materials. In this work, Raman spectra were studied using Thermo Scientific DXR Raman microscope (Figure 3.8) with a He – Ne laser in  $100 - 1000 \text{ cm}^{-1}$  for wavenumber.

Figure 3.8 Thermo Scientific DXR Raman microscope [7]

### 3.3.2 Electrical Analysis

#### 3.3.2.1 Sample preparation

Before the measurement of electric properties, all samples were polished for both sides and made parallel. They were cleaned with ethanol in an ultrasonic bath before electrode coating with silver paste (C1000, Heraeus) on both surfaces. Silver paste was heated on at 750°C for 20 min with heating/cooling rate 5°C/min and before measurement of the piezoelectric constant  $d_{33}$  poling of the sample was done.

#### 3.3.2.2 Dielectric property measurement [5]

The dielectric property measurement are mention the determination of the phase transition temperature, relative permittivity ( $\epsilon_r$ ) or dielectric constant and loss tangent ( $\tan\delta$ ). The relative permittivity and loss tangent value were determined from capacitance measurements based on the following equation 3.5.

$$C = \frac{\epsilon_0 \epsilon_r A}{d} \quad (3.5)$$

Where  $C$  is the capacitance (Farad),  $d$  is the ceramic thickness,  $A$  is the surface area of sample, and  $\epsilon_0$  is the permittivity of free space,  $8.854 \times 10^{-12}$  F/m.

**Figure 3.9** LCR analyzer (HP – 4284, Hewlette Packard Inc.)

In this work, the dielectric property measurements were done using programmable furnace with an LCR analyzer (HP – 4284, Hewlette Packard Inc.), as shown in figure 3.9 and temperature varied at room temperature to 250°C for BT–BNT–xBMT ceramics and at room temperature to 160°C for BT–ST–yBS ceramics.

### 3.3.2.3 Ferroelectric property measurement

Ferroelectric material are perform measurement of polarization as a function of electric field ( $P - E$  hysteresis loop). The  $P - E$  hysteresis loop describes the dynamic nonlinear polarization switch behavior as a function of field. The spontaneous polarization ( $P_s$ ), remnant polarization ( $P_r$ ) and coercive field ( $E_c$ ) can be obtained from ferroelectric hysteresis loop. In this studies, polarization – electric field ( $P - E$ ) hysteresis loop were determined at room temperature using Radiant Technologies, Inc (RT66A) at a frequency

4 Hz and an electric field of 10 – 60 kV/cm. During the measurement, the samples were immersed in silicone oil to prevent the breakdown of from the side area of the samples.

Figure 3.10 Ferroelectric Tester

### 3.3.2.4 Piezoelectric property measurement [6]

The piezoelectric properties mention the piezoelectric constant ( $d$  coefficient). These is the polarization generated per unit of mechanical stress applied to material (Direct effect) alternatively, is the mechanical strain produced by a piezoelectric material per unit of electric field applied (Converse effect). The  $d$  coefficient can be calculated from the following equation 3.6 and 3.7.

$$d_{ij} = \frac{\text{short circuit charge density}}{\text{applied mechanical stress}} \quad (C/N) \quad (3.6)$$

$$= \frac{\text{mechanical strain}}{\text{applied electric field}} \quad (m/V) \quad (3.7)$$

Where  $i$  indicates the direction of electric field or displacement and  $j$  indicates the direction of mechanical stress or strain.

Figure 3.11 Instrument for strain measurement

In this work, the piezoelectric property, the strain measurement was done using an optical displacement sensor (MTI-2100) combined with the radiant ferroelectric test system at room temperature and an external electric field of 20 and 60 kV/cm. The normalized strain ( $d_{33}^*$ ) value was calculated from the  $\frac{S_{max}}{E_{max}}$  ratio for each composition. For the  $d_{33}$  measurements was determined at room temperature by using directly from a quasistatic  $d_{33}$  meter (YE2730A, APC International Ltd.). Before  $d_{33}$  measurements, the ceramics were poled at room temperature in silicone oil by applying a DC field at 35 – 40 kV/cm for 20 minutes.

## CHAPTER 4

# EFFECT OF Sn CONTENT ON THE DIELECTRIC AND PIEZOELECTRIC PROPERTIES OF THE TERNARY SYSTEM (0.975-y)BaTiO<sub>3</sub>-0.025SrTiO<sub>3</sub>-yBaSnO<sub>3</sub>

Based on article published in Journal of Materials Science

Design of the polymorphic phase composition in the (0.975-y)BaTiO<sub>3</sub>-0.025SrTiO<sub>3</sub>-yBaSnO<sub>3</sub> ternary system was based on the ferroelectric phase diagram. The dense ceramic of (0.975-y)BaTiO<sub>3</sub>-0.025SrTiO<sub>3</sub>-yBaSnO<sub>3</sub> with  $y = 0.00, 0.02, 0.04, 0.06, 0.08$  and  $0.10$  compositions was fabricated successfully via the solid state reaction method. The effect of Sn substitution on the ferroelectric phase transition and piezoelectric properties was explored in order to achieve high performance piezoelectric properties. All of the ceramics exhibited pure perovskite structures. Orthorhombic to tetragonal phase transition was evidenced clearly as a function of Sn content. The orthorhombic to tetragonal phase transition shifted close to ambient temperature by increasing the Sn content. The coexistent tetragonal and orthorhombic phases were exhibited at the composition,  $y = 0.04$ , and showed outstanding dielectric and piezoelectric properties, relative permittivity ( $\epsilon_r$ ) of 11500 and piezoelectric coefficient ( $d_{33}$ ) of 450 pC/N. An outstanding reversible strain of about 0.12%, with a normalized piezoelectric coefficient ( $S_{\max}/E_{\max}$ ) of 1,280 pm/V at a low electric field (10 kV/cm), was observed clearly at the composition of the coexistent phase. The (0.975-y)BaTiO<sub>3</sub>-0.025SrTiO<sub>3</sub>-yBaSnO<sub>3</sub> ceramics are the most promising candidate for lead-free piezoelectric materials.

### 4.1 Introduction

Lead-based piezoelectric ceramics such as lead zirconate titanate [Pb(Zr<sub>1-x</sub>Ti<sub>x</sub>)O<sub>3</sub>; PZT] have been used most widely in actuator and sensor devices, due to their excellent piezoelectric properties [1]. Nevertheless, PZT ceramics are environmentally unfriendly and dangerous to human health, due to the toxicity of lead in fabrication

processing [2, 3]. Therefore, attention has been drawn to lead-free piezoelectric materials with a performance comparable to that in lead-based materials. Consequently, in recent years diverse systems have been explored, including bismuth – alkaline metal titanates and niobates, and especially BaTiO<sub>3</sub>; BT solid solution [2–5].

Ferroelectric behavior was discovered in Barium titanate (BaTiO<sub>3</sub>; BT) by Wul and Goldman in 1946 [6], which led to the widespread use of BT in capacitors and electromechanical devices [6, 7]. BT has a tetragonal perovskite structure at room temperature, and pure BT exhibits a piezoelectric constant ( $d_{33}$ ) of about 191 pC/N [8] that is relatively low when compared to PZT-based ( $d_{33} = 300 - 600$  pC/N) [8]. Therefore, BT has been modified by doping with A and/or B site substitutions [9–11]. The binary system of BaTiO<sub>3</sub>–BaSnO<sub>3</sub>; BT–BSn recently showed high dielectric permittivity ( $\epsilon_r$ )  $\sim 75000$  and excellent piezoelectric coefficient ( $d_{33}$ )  $\sim 697$  pC/N at the quasi-quadruple point, which exhibited coexistent Cubic–Tetragonal–Orthorhombic–Rhombohedral phases in BT–BSn [12]. Wang et al. [13] reported a high electrostriction strain of  $\sim 0.22\%$  in the binary systems of BaTiO<sub>3</sub>–CaTiO<sub>3</sub>; BT–CT. Excellent piezoelectric properties also were obtained in the coexistent phase composition in the BaTiO<sub>3</sub>–BaZrO<sub>3</sub>–CaTiO<sub>3</sub>; BT–BZ–CT and BaTiO<sub>3</sub>–BaZrO<sub>3</sub>–CaTiO<sub>3</sub>; BT–BS–CT system [9, 14]. The (Ba<sub>1-x</sub>Ca<sub>x</sub>)(Ti<sub>0.92</sub>Sn<sub>0.08</sub>)O<sub>3</sub> ceramics recently displayed high  $d_{33} = 568$  pC/N,  $k_p = 47.7\%$ ,  $\epsilon_r = 23,000$  and normalized strain (dS/dE) = 1013 pm/V at the orthorhombic/tetragonal coexistent phase composition [15]. The coexistent phase composition in the Sn dope BT–CT system also exhibited ultra-high  $d_{33}$  (670 pC/N) and electrostrain (0.061%) [16]. Li et al. [17] recently reported a high piezoelectric coefficient ( $d_{33}$ ) of about 380 pC/N and  $k_p$  of about 38% in the Sr dope Ba(Zr,Ti)O<sub>3</sub>; BZT system. The Sr substitute BZT, not only enhanced piezoelectric properties by shifting the ferroelectric phase transition close to room temperature, but also decreased the sintering temperature of the ceramic. In order to find new BT-based ceramics with excellent piezoelectric properties, Sn cation was selected to substitute the Sr-doped BaTiO<sub>3</sub> in this work. Sr doped BT was used as a base composition, due to Sr being able to enhance piezoelectric properties and slightly decrease the sintering temperature of the ceramic. Systematic study of how the Sn substitution affects crystal structure, and dielectric and piezoelectric behavior of (0.975-y)BaTiO<sub>3</sub>–0.025SrTiO<sub>3</sub>–yBaSnO<sub>3</sub>; BT–ST–yBS ceramics, is still rare. The BT–ST–yBS ceramic, with  $y = 0.00, 0.02, 0.04, 0.06, 0.08$  and  $0.10$  compositions, is designated in this study as a lead-free

composition that explores the compositional dependence of structure and piezoelectric behavior in Sn content. The development of piezoelectric properties by optimizing Sn content in BT–ST–yBS ceramics has been established.

## 4.2 Experimental procedure

The  $(0.975-y)\text{BaTiO}_3-0.025\text{SrTiO}_3-y\text{BaSnO}_3$  ceramic with  $y = 0.00, 0.02, 0.04, 0.06, 0.08$  and  $0.10$  compositions was fabricated via the solid–state reaction technique. The metal carbonate and oxide powder of  $\text{BaCO}_3$  (99.9%, Inframal Advance Materials),  $\text{SrCO}_3$  (99.5%, Inframal Advance Materials),  $\text{TiO}_2$  (99.9%, Sigma-Aldrich) and  $\text{SnO}_2$  (99.9%, Inframal Advance Materials) were used as raw materials. The stoichiometric amount of starting materials was mixed in ethanol with yttrium-stabilized zirconia in the first step, and then vibro-milled for 6 hours. The mixtures were dried and calcined at temperatures between 1,200 and 1,300°C for 4 hours, with a heating/cooling rate of 5°C/min. The calcined powders were ground and sieved. Finally, the resultant powders were pressed into pellets of 10 mm diameter, using 5 wt% polyvinyl alcohol (PVA) as a binder. The pellets were sintered at between 1,375 and 1,450°C for 4 hours with a heating/cooling rate of 5°C/min. Ceramics with more than 94% theoretical density were selected for investigating electrical properties. The crystal structure of ceramics was carried out with X-ray diffraction (Bruker-AXS D 8 Advance) using  $\text{CuK}\alpha$  radiation in the  $2\theta$  scan range of 20°–80°. In order to support crystal structure identification of the ceramics, Raman spectra were measured in the 100 – 1,000  $\text{cm}^{-1}$  wave number range with a Thermo Scientific DXR Raman microscope, using the 532 nm exciting line of a He-Ne laser. Both sides of the samples were polished and paralleled for electrical measurements. Then, the pellets were coated on both surfaces with silver electrodes (C1000, Heraeus) and heated at 750°C for 20 min, with a heating/cooling rate of 5°C/min. The frequency (1, 10, 100 kHz) and temperature (room temperature to 160°C) dependence of relative permittivity ( $\epsilon_r$ ) and dielectric loss ( $\tan\delta$ ) were obtained by using an LCR analyzer (HP4284A, Hewlett-Packard, Palo Alto, CA). Ferroelectric hysteresis loops were determined at room temperature by using a ferroelectric tester (RT66A, Radiant Technologies, Inc.), and the strain – electric field (S – E) loop was measured by unipolar driving at 4 Hz using an MTI-2100 Fotonic sensor combined with a ferroelectric tester. The pellets of 10 mm diameter and 0.6 mm thickness were poled

under a DC field at 35 – 40 kV/cm for 30 min at room temperature and aged for 24 hours before piezoelectric measurements. The piezoelectric coefficient,  $d_{33}$ , was characterized using a quasi-static  $d_{33}$  meter (YE2730A, APC International Ltd.).

### 4.3 Results and discussion

The characteristics of crystal structured ceramics were examined by X-ray diffraction (XRD). XRD patterns of the BT–ST–yBS system, with compositions of  $y = 0.00, 0.02, 0.04, 0.06, 0.08$  and  $0.10$ , are shown in Fig. 4.1a–d. All of the samples demonstrated a single phase with the perovskite structure, and the secondary or impure phase was not observed in the XRD patterns, which indicates that both Sr and Sn ions are fully diffused into the BaTiO<sub>3</sub> lattice to form solid solution. The crystal structure of BT–ST–yBS at the compositions,  $0.00 \leq y \leq 0.02$ , has a tetragonal symmetry, identified by a single peak at  $2\theta$  of  $38.7^\circ$  (Fig. 4.1b) and splitting of (002) and (200) peaks at  $2\theta$  of  $44.8 - 45.6^\circ$  (Fig. 4.1c). At higher compositions of  $0.06 \leq y \leq 0.10$ , the XRD pattern exhibits splitting of two peaks [(102)/(120)] at around  $38 - 39.5^\circ$  and splitting of three peaks [(113)/(131)/(202)] at around  $55.8 - 56.3^\circ$ , which indicates an orthorhombic symmetry (Fig. 4.1d). Therefore, the results indicated that the crystal structure changed from tetragonal to orthorhombic phase with increasing Sn content. Meanwhile, it is anticipated that the tetragonal and orthorhombic phases for  $y = 0.04$  coexist, which is confirmed by dielectric and piezoelectric measurements. It is seen clearly that the diffraction pattern of all compositions shifts gradually to low angles with increasing Sn content, which should induce expansion of the host lattice. Lattice parameter ( $\text{\AA}$ ) and unit cell volume ( $\text{\AA}^3$ ) were calculated and plotted as a function of Sn content, as shown in Fig. 4.2a, b. Regarding the compositions,  $0.00 \leq y \leq 0.02$ , with tetragonal symmetry, the unit cell  $a$  and  $c$  increase slightly with increasing Sn content, which corresponds with increased unit cell volume. The ostensibly discontinuous changes are noticed at  $0.02 \leq y \leq 0.06$  when the tetragonal and orthorhombic phases coexist. The orthorhombic lattice parameters ( $a$ ,  $b$  and  $c$ ) and unit cell volume slightly increase for the compositions,  $0.06 \leq y \leq 0.10$ . This is consistent with the result reported by Zhu et al. [16]. The increase in the lattice parameter is caused mainly by the majority of Sn ions substitute  $\text{Ti}^{4+}$  ions the B site of the perovskite structure with  $\text{Sn}^{4+}$  state. However, it should be noted that the valency of the Sn ion is very sensitive

and allowed to adapt to a divalent, trivalent and tetravalent state in oxide ceramics [18]. Suzuki et al. [19] reported that under sintering conditions of reducing atmosphere, the Sn ions can substitute  $Ba^{2+}$  ions at the A-site of the perovskite structure with  $Sn^{2+}$  state. The oxidation states of the Sn ion in BT–ST–yBS ceramics must be considered for future investigation.

**Figure 4.1** (a) X-ray diffraction patterns of  $(0.975-y)BaTiO_3-0.025SrTiO_3-yBaSnO_3$  ceramic between the  $2\theta$  range of 20 – 80°, (b) expanded range of 38 – 39.5°, (c) expanded range of 44.8 – 45.6°, and (d) expanded range of 55.8 – 56.3°

Figure 4.2 The relative plot between the (a) lattice parameter (Å), and (b) cell volume (Å<sup>3</sup>) and composition y in (0.975-y)BaTiO<sub>3</sub>-0.025SrTiO<sub>3</sub>-yBaSnO<sub>3</sub> ceramic.

Dependence on the composition of Raman spectra for  $(0.975-y)\text{BaTiO}_3-0.025\text{SrTiO}_3-y\text{BaSnO}_3$  systems was investigated at room temperature in the frequency range of  $100-1,000\text{ cm}^{-1}$ , as shown in Figure 4.3(a-d). The ferroelectric phase with tetragonal symmetry corresponds with group theory analysis in normal optical mode, with each  $F_{1u}$  mode transforming into  $A_1$  and E modes, whereas the  $F_{2u}$  mode gives rise to  $B_1$  (silent) and E modes. All spectra generally display Raman-active modes of ferroelectric material. The interference dips at around  $180\text{ cm}^{-1}$ , due to antiresonance between sharp  $A_1(\text{TO}_1)$  and broad  $A_1(\text{TO}_2)$  modes; such as a broad peak of  $A_1(\text{TO}_2)$  mode near  $257\text{ cm}^{-1}$ ; sharp peak of  $E(\text{TO}_2)$  mode at  $295\text{ cm}^{-1}$ ; broad peak of  $A_1(\text{TO}_3)$  and  $E(\text{TO})$  mode at around  $515\text{ cm}^{-1}$ , which is a bending and stretching vibration of symmetric Ti-O in  $[\text{TiO}_6]^{2-}$  and a broad peak of  $A_1(\text{LO}_3)/E(\text{LO}_3)$  mode at around  $712\text{ cm}^{-1}$ [20]. Therefore, Raman spectra of all compositions are observed at a broad peak of  $A_1(\text{TO}_2)$ ,  $E(\text{TO}_2)$ ,  $A_1(\text{TO}_3)/E(\text{TO})$ ,  $A_1(\text{LO}_3)/E(\text{LO}_3)$  and interference dip mode (Figure 4.3a), which indicates that all compositions exhibit ferroelectric phase. The signature Raman mode of tetragonal phase for BT is generally; a broad  $A_1(\text{TO}_2)$  mode, sharp  $E(\text{TO}_2)$  mode, broad  $A_1(\text{TO}_3)/E(\text{TO})$  mode, swelling  $A_1(\text{LO}_2)/E(\text{LO})$  mode and broad  $A_1(\text{LO}_3)/E(\text{LO}_3)$  mode [21]. Also, the mode of orthorhombic phase is a broad  $A_1(\text{TO}_1)$ ,  $A_1(\text{TO}_2)$ ,  $A_1(\text{TO}_3)/E(\text{TO})$  and  $A_1(\text{LO}_3)/E(\text{LO}_3)$  peak and sharp  $E(\text{TO}_2)$  peak [21]. In the compositions,  $0.00 \leq y \leq 0.02$ , all of the Raman patterns show  $A_1(\text{TO}_2)$ ,  $E(\text{TO}_2)$ ,  $A_1(\text{LO}_2)/E(\text{LO})$ ,  $A_1(\text{TO}_3)/E(\text{TO})$  and  $A_1(\text{LO}_3)/E(\text{LO}_3)$  at around  $260$ ,  $303$ ,  $472$ ,  $517$  and  $720\text{ cm}^{-1}$ , respectively, which indicates a ferroelectric tetragonal phase. At the higher compositions,  $0.04 \leq y \leq 0.10$ , the  $A_1(\text{TO}_1)$  mode appeared gradually at  $190\text{ cm}^{-1}$  and  $A_1(\text{LO}_2)/E(\text{LO})$  mode at  $472\text{ cm}^{-1}$ , but both were absent in the Raman spectrum. Therefore, the compositions,  $0.06 \leq y \leq 0.10$ , were considered as a signature of the ferroelectric orthorhombic phase by the presence of  $A_1(\text{TO}_1)$ ,  $A_1(\text{TO}_2)$ ,  $E(\text{TO}_2)$ ,  $A_1(\text{TO}_3)/E(\text{TO})$  and  $A_1(\text{LO}_3)/E(\text{LO}_3)$  mode near  $190$ ,  $222$ ,  $301$ ,  $514$  and  $716\text{ cm}^{-1}$ , respectively. A weak  $A_1(\text{TO}_1)$ ,  $A_1(\text{TO}_2)$ ,  $E(\text{TO}_2)$ ,  $A_1(\text{TO}_3)/E(\text{TO})$  and  $A_1(\text{LO}_3)/E(\text{LO}_3)$  peak at the composition,  $y = 0.04$ , showed coexistence of the ferroelectric tetragonal and orthorhombic phase. These results identified that the phase transition changed from tetragonal to orthorhombic phase, which corresponds well with the XRD pattern.

Figure 4.3 (a) Raman spectra of  $(0.975-y)\text{BaTiO}_3-0.025\text{SrTiO}_3-y\text{BaSnO}_3$  ceramic at room temperature with the compositions,  $0.00 \leq y \leq 0.10$ , in the wave number range from 100 to 1,000  $\text{cm}^{-1}$ , (b) enlarged Raman shift range from 100 to 290  $\text{cm}^{-1}$ , (c) enlarged Raman shift range from 200 to 310  $\text{cm}^{-1}$ , and (d) the relative plot between wave number  $\text{cm}^{-1}$  and composition  $y$ .

Figure 4.4 presents the temperature dependence of relative permittivity ( $\epsilon_r$ ) and dielectric loss ( $\tan\delta$ ) of BT–ST–yBS systems with  $y = 0.00, 0.02, 0.04, 0.06, 0.08$  and  $0.10$  compositions at frequencies 1, 10 and 100 kHz. The relative permittivity curves for the composition,  $y = 0.00$  and  $0.02$ , exhibit one sharp peak at  $110$  and  $97^\circ\text{C}$ , respectively, with this transition being related to the transition from tetragonal (P4mm) ferroelectric to cubic (Pm3m) paraelectric phase. Nevertheless, the relative permittivity curves for the compositions,  $0.04 \leq y \leq 0.08$ , presented two anomalous peaks. A higher temperature was associated with the ferro-to-paraelectric phase transition, while a lower temperature suggested the phase transition from orthorhombic to tetragonal phase. The O–T phase transition temperature shifted slightly with increasing Sn content to a high temperature from  $32^\circ\text{C}$  for  $y = 0.04$  –  $41^\circ\text{C}$  for  $y = 0.08$ . Furthermore, the transition temperature decreases with increasing Sn content (Fig. 4.5). The temperature range width of the tetragonal phase decreases continuously with increasing Sn content. The permittivity at room temperature is seen to increase continuously from  $y = 0.00$  –  $0.04$  with increasing Sn content. This result is due to the shift of O–T phase transition temperature that is close to room temperature. It is known that the relative permittivity of a normal ferroelectric phase, which is above the maximum relative permittivity temperature, can be described by the Curie – Weiss law [7, 22];

$$\frac{1}{\epsilon_r} = \frac{C}{T - T_0}; \quad (T > T_0) \quad (4.1)$$

where  $T_0$  is the Curie – Weiss temperature and  $C$  is the Curie – Weiss constant. The relative permittivity of pure BT obeys the Curie – Weiss law, which is  $T_0 \sim 383$  K and  $C \sim 1.56 \times 10^5$  K [14]. However, further characterization of broad relative permittivity and diffuseness of the phase transition followed a modified Curie-Weiss law, as described below [23, 24]:

$$\frac{\epsilon_m}{\epsilon} = 1 + \frac{(T - T_m)^\gamma}{2\delta_\gamma^2}; \quad (T > T_m) \quad (4.2)$$

where  $\gamma$  is constant and  $\epsilon_m$  is the maximum value of relative permittivity at phase transition temperature ( $T_m$ ). The parameter  $\gamma$  expresses information on the character of the phase transition, and when  $\gamma = 1$ , the equation follows the Curie – Weiss law, which indicates normal ferroelectrics; while  $\gamma = 2$  describes a complete diffuse phase transition. The  $\delta$  value can be applied to gauge the degree of diffuseness in the phase

transition. Figure 4.6 illustrates the plot of  $\ln\left(\frac{1}{\varepsilon} - \frac{1}{\varepsilon_m}\right)$  as a  $\ln(T - T_m)$  function of  $(0.975-y)\text{BaTiO}_3-0.025\text{SrTiO}_3-y\text{BaSnO}_3$  systems at 1 kHz. The value of parameter  $\gamma$  and  $\delta$  is presented in Table 1. It can be seen that parameter  $\gamma$  tends to increase from 1.20 to 1.37 with increasing Sn content. The  $\delta$  value has a similar tendency of an increase from 12.47 to 13.40 with increasing Sn content, thus confirming that a diffuse phase transition appears in the BT-ST-yBS system. This result occurs when at least two cations dominate the same crystallographic site, a or b, which is found in many complex perovskite structures such as lead-free  $\text{BaZrO}_3-\text{CaTiO}_3-\text{BaTiO}_3$  [11],  $\text{K}_{0.5}\text{Na}_{0.5}\text{NbO}_3-\text{LiSbO}_3$  [25] and  $(\text{Ba}_{0.85}\text{Ca}_{0.15})(\text{Zr}_{0.1}\text{Ti}_{0.9})\text{O}_3-\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  [26].

In order to investigate the ferroelectric behavior in BT–ST–yBS ceramics, the electrical polarization hysteresis loop of each composition was measured at room temperature with an electric field of 60 kV/cm. Figure 4.7a illustrates the polarization–electric field hysteresis loop for all compositions of  $y$  at a frequency of 4 Hz. All BT–ST–yBS ceramics with  $y = 0.00$ – $0.10$  compositions exhibit symmetry in shape and well-saturated hysteresis loops and result in domain switching in an electric field. The plot of  $P_r$  and  $E_c$  value as a function of composition  $y$  is presented in Fig. 4.7b. It can be seen that the  $P_r$  initially tends to increase from  $12.93 \mu\text{C}/\text{cm}^2$  at  $y = 0.00$  to a maximum value of  $13.14 \mu\text{C}/\text{cm}^2$  at  $y = 0.04$ , and then it decreases gradually from  $10.48 \mu\text{C}/\text{cm}^2$  at  $y = 0.06$  –  $6.95 \mu\text{C}/\text{cm}^2$  at  $y = 0.10$ . In addition, the  $E_c$  values decrease clearly from 7.00 to 3.08 kV/cm with increasing Sn content, as shown in Fig. 4.7b. The decrease in  $E_c$  indicates that ceramics become “softer” with increasing Sn content, regarding the electric field, because the free energy profile for polarized rotation is flattened anisotropically at the two phases and multiphase coexistence [12, 27]. In order to investigate the changes in hysteresis loop behavior, the empirical relationship between  $P_r$ ,  $P_s$  and polarization at fields above  $E_c$  was proposed by Haertling and Zimmer for calculating squareness of the hysteresis loop as follows [28]:

$$R_{\text{sq}} = \frac{P_r}{P_s} + \frac{P_{1.1E_c}}{P_r} \quad (4.3)$$

where  $R_{\text{sq}}$  is the squareness of the hysteresis loop, and  $P_r$  and  $P_s$  are remanent and saturated polarization, respectively.  $P_{1.1E_c}$  is polarization at an increasing electric field of 1.1 times the coercive field ( $E_c$ ). The squareness parameter investigates the quantification of changes in P–E hysteresis loops. The  $R_{\text{sq}}$  is equal to 2 for an ideal P–E hysteresis loop. The calculated  $R_{\text{sq}}$  values of all ceramics are inferred in Table 4.1. It was found that the  $R_{\text{sq}}$  parameter tended to decrease from 0.80 to 0.72 with increasing Sn content, which implies that the P – E hysteresis loop becomes more slanted.

Figure 4.8a displays the unipolar electric field induced strain curve for the BT–ST–yBS ceramic, with  $y = 0.00$  –  $0.10$  compositions, measured at 10 kV/cm. It can be observed that with increasing Sn content, the unipolar strain increases with increasing  $y$  of up to 0.04 and reaches the maximum electrostrain value of 0.13%. On increasing  $y$  further to 0.1, the unipolar strain decreases to 0.074%. Figure 4.8b illustrates the

direct piezoelectric coefficient ( $d_{33}$ ) and a normalized strain or converse piezoelectric coefficient ( $d_{33}^* = S_{\max}/E_{\max}$ ) at the electric field of 10 kV/cm as a function of composition. It can be observed that the  $d_{33}^*$  value tends to increase with increasing composition  $y$  and reaches its maximum at about 1280 pm/V at  $y = 0.04$ , before decreasing with increasing composition  $y$ . The  $d_{33}$  values also have a similar trend and maximum  $d_{33}$  values of 450 pC/N, as  $y$  increases to 0.04. As a result, ceramic at the composition,  $y = 0.04$ , exhibits the highest normalized strain and piezoelectric constant in the systematic series studied, due to the coexistence of orthorhombic and tetragonal phase near room temperature. The enhanced  $d_{33}$  and  $d_{33}^*$  values are considered to be reasonably consistent with the multiphase coexistence of the orthorhombic and tetragonal phase that occurs near ambient temperature at  $y = 0.04$ . In the point view of crystallographic symmetry, there are 18 domain orientation states (6 domain states along 100c direction for tetragonal symmetry and 12 along 110c direction for orthorhombic symmetry) near the O–T phase transitions. In general, a large number of thermodynamically equivalent states near O–T phase transitions allow a high degree of ferroelectric dipole alignment. This causes instability, multiple polarization and strain variants, so that the direction of polarization is rotated easily by external stress or the electric field, thus making it much easier for different grains to coordinate in a collective response.

Figure 4.7 (a) The plot between polarization ( $\mu\text{C}/\text{cm}^2$ ) and electric field (kV/cm) as a function of composition  $y$ , and (b) the plot of remanant polarization ( $\mu\text{C}/\text{cm}^2$ ) and coercive field (kV/cm) value as a function of composition  $y$ .

Figure 4.8 (a) The relative plot between unipolar strain (%) and electric field (kV/cm) as a function of composition, and (b) the plot of normalized strain ( $d_{33}^*$ (pm/V)) and piezoelectric constant ( $d_{33}$ (pC/N)) value as a function of composition  $y$ .

#### 4.4 Conclusion

BT-ST-yBS ceramic was fabricated by the conventional solid – state reaction method. Raman and XRD study indicates that the orthorhombic and tetragonal phases coexist near ambient temperature at  $y = 0.04$ . Enhanced dielectric, ferroelectric and piezoelectric properties of  $\epsilon_{r \max} \sim 11500$ ,  $P_r \sim 13.14 \mu\text{C}/\text{cm}^2$ ,  $d_{33}^* \sim 1280 \text{ pm}/\text{V}$  and  $d_{33} \sim 450 \text{ pC}/\text{N}$  were obtained as samples at  $y = 0.04$ . This observation indicated that the BT-ST-yBSn system is a promising candidate for lead-free piezoelectric ceramics.

# CHAPTER 5

## DIELECTRIC, FERROELECTRIC AND PIEZOELECTRIC PROPERTIES OF THE LEAD FREE $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$ SOLID SOLUTION

Based on article published in *Ferroelectrics*

Solid solution of  $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  (BT–BNT–xBMT) system, where  $x = 0.00, 0.02, 0.04, 0.06, 0.08, 0.10$ , was synthesized by the solid state reaction. Dense BT–BNT–xBMT ceramics were obtained by sintering at  $1,150-1,250^\circ\text{C}$  for 4 h. The effect of BMT on crystal structure and electrical property of BT–BNT ceramics was investigated as a function of composition,  $x$ , using X-ray diffraction, dielectric spectroscopy, hysteresis and strain measurements. The crystal structure of solid solution BT–BNT–xBMT, where  $x = 0.00-0.10$ , successively transforms from tetragonal to pseudocubic symmetry, with increased BMT concentration. Temperature dependence of dielectric constant ( $\epsilon_r$ ) and dielectric loss ( $\tan\delta$ ) for BT–BNT–xBMT at various frequencies showed that phase transition of ceramics changed from ferroelectric to relaxor-like behavior as BMT content increased. Furthermore, remanent polarization ( $P_r$ ), coercive field ( $E_c$ ) and the normalized strain ( $d_{33}^*$ ) of BT–BNT–xBMT ceramics tend to decrease with increasing BMT concentration.

### 5.1 Introduction

Lead zirconate titanate (PZT) ceramics have been used widely in many electronic devices such as piezoelectric sensor, actuators and transducers because of their excellent piezoelectric properties [1]. However, PZT-based piezoelectric ceramics are not environmental friendly because more than 60% wt of these ceramics contains the lead toxicity. Furthermore, the EU legislation forced draft directives including Waste from Electrical and Electronic Equipment (WEEE) and Restriction of Hazardous Substances (RoHS). According to the environmental issues, lead free friendly

piezoelectric ceramics have been received considerable attentions to replace lead-based piezoelectric materials.

Although no real lead free materials can be replaced the common use in lead-based ceramics for various applications, many potentially promising lead free materials have been developed. Among the lead free materials, Barium titanate ( $\text{BaTiO}_3$ ; BT) has perovskite structure and good electrical properties such as ferroelectric and piezoelectric properties but low Curie temperature ( $T_C$ ) [2]. In recent years, there are many researches about BT-base for example  $\text{Ba}_{0.85}\text{Ca}_{0.15}\text{Ti}_{0.90}\text{Zr}_{0.10}\text{O}_3$  [3] and  $(1-x)\text{Ba}_{0.98}\text{Ca}_{0.02}\text{Ti}_{0.94}\text{Sn}_{0.06}\text{O}_3-x\text{Ba}_{0.85}\text{Ca}_{0.15}\text{Ti}_{0.90}\text{Zr}_{0.10}\text{O}_3$  [4]. Jiagang Wu *et al.* [4] found that BT-base ceramic by combining  $(1-x)\text{Ba}_{0.98}\text{Ca}_{0.02}\text{Ti}_{0.94}\text{Sn}_{0.06}\text{O}_3-x\text{Ba}_{0.85}\text{Ca}_{0.15}\text{Ti}_{0.90}\text{Zr}_{0.10}\text{O}_3((1-x)\text{BCTS}-x\text{BCTZ})$  system has a phase boundary coexistence of orthorhombic and tetragonal phase at around 4 mol% BCTZ which show good dielectric and piezoelectric properties of dielectric constant ( $\epsilon_r \sim 5500$ ), dielectric loss ( $\tan\delta \sim 0.3\%$ ) and piezoelectric constant ( $d_{33} \sim 407$  pC/N). The binary system of  $\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3\text{-BaTiO}_3$  (BNT-BT) is an important candidate for replacing lead-based piezoelectric. In a few decades, BNT-BT solid solution was studied by various research groups [2,5,6]. Takenaka *et al.* [5] found that BNT-BT system has a morphotropic phase boundary (MPB) between rhombohedral and tetragonal phases at around 6-7 mol% BT which shows the excellent properties including  $\epsilon_{33}^T/\epsilon_0 = 580$ , piezoelectric constant ( $d_{33} = 125$  pC/N), Curie temperature ( $T_C = 288^\circ\text{C}$ ), dielectric loss ( $\tan\delta = 1.3\%$ ) and planar coupling coefficient ( $k_{33} = 55.0\%$ ). Afterwards, researchers focused to develop BNT-BT binary material on the composition range of MPB by doing ternary solid solution such as KNN-modified BNT-BT [7,8] and BZr-modified BNT-BT [9]. Also, the BNT-BT based systems on the BNT-rich side have been investigated extensively for example  $(0.94-x)\text{BNT}-0.06\text{BT}-x\text{KNN}$  [7],  $0.865\text{BNT}-0.350\text{BT}-0.100\text{BKT}$  [8] and BZr-modified BNT-BT [9]. However, few works have investigated and developed BNT-BT on the BT-rich side. Recently, Wada *et al.* studied on the combination between  $\text{BaTiO}_3$  and  $\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  (BMT) and found that BMT can enhance Curie temperature ( $T_C$ ) of BT with the highest  $T_C$  (about  $360^\circ\text{C}$ ) for  $0.5\text{BaTiO}_3\text{-}0.5\text{BMT}$  ceramics [10]. Moreover, Qi Wang *et al.* have studied lead free  $\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3\text{-Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  systems and reported that BMT can improve piezoelectric properties and enhance  $T_C$  of BNT ceramic. The  $0.95\text{BNT}-0.05\text{BMT}$  ceramic showed the highest  $d_{33}$  about 110 pC/N and high  $T_C$  at  $352^\circ\text{C}$  [11].

This work dealt with the new ternary system of  $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  in order to get more information of BT–BNT-based on BT–rich side. BT–BNT–xBMT ceramics were prepared by the solid state reaction. The effect of BMT on crystal structure, phase transition and electrical properties were studied as a function of composition,  $x$ .

## 5.2 Experimental procedure

Lead free  $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  (BT–BNT–xBMT) ceramics, where  $x = 0.00, 0.02, 0.04, 0.06, 0.08, 0.10$ , were synthesized by the solid state reaction.  $\text{Bi}_2\text{O}_3$  (99.9%, Sigma-Aldrich),  $\text{BaCO}_3$  (98.5%, Fluka),  $\text{Na}_2\text{CO}_3$  (99.8%, Riedel-deHaen),  $\text{TiO}_2$  (99.9%, Sigma-Aldrich) and  $\text{MgO}$  (99%, Fluka) powders were used raw materials. First, stoichiometric amounts of raw materials were weighted and ball-milled with yttrium-stabilized zirconia in ethanol media for 18 hours. After drying the mixture for 24 hours in an oven, the mixed powder was calcined at 900 for 4 hours with heating/cooling rate  $10^\circ\text{C}/\text{min}$ . In order to obtain fine particles prior to making a pellet, the calcined powders were ground and sieved. The fine powders were pressed into disks with 15 mm diameter. 5 wt% polyvinyl alcohol as a binder was used as binder. The disks were sintered at 1150 – 1250°C for 4 hours with heating/cooling rate  $5^\circ\text{C}/\text{min}$ . The crystal structure of ceramics was characterized using X–ray diffraction (Bruker – AXS D 8 Advance) with  $\text{Cu}(\text{K}\alpha)$  radiation in the  $2\theta$  scan range of 20 – 80°. For electrical measurements, the samples were polished for both sides and made parallel before electrode coating with silver paste (C1000, Heraeus) on both surfaces. Silver paste was heated on at 750°C for 20 mins with heating/cooling rate  $5^\circ\text{C}/\text{min}$ . The relative permittivity ( $\epsilon_r$ ) and dielectric loss ( $\tan\delta$ ) were determined as a function of frequency (1 – 100 kHz) and temperature (room temperature to 250°C) using LCR meter (HP4284A, Hewlett-Packard, Palo Alto, CA). Polarization-electric field (P – E) hysteresis loop were determined at room temperature using Radiant Technologies, Inc (RT66A). The strain-electric field (S – E) curves were determined using MTI-2100 Fotonic sensor combined with Radiant Technologies. The peak field for P – E hysteresis loop and S – E curve measurements was maintained at 60 kV/cm during measurement. The surface morphology of ceramics was observed using scanning electron microscope (EVO®MA10).

### 5.3 Results and discussion

The X-ray diffraction patterns of BT–BNT–xBMT ceramics, where  $x = 0.00, 0.02, 0.04, 0.06, 0.08, 0.1$ , are shown in Figure 5.1(a). It indicates that all samples are a single phase with the perovskite structure. The secondary and other phases were not observed in the XRD patterns, which indicates that all compositions in the BT–BNT–xBMT system can completely form solid solution with a perovskite structure. A (111) peak at around  $39^\circ$  was chosen to identify the crystal structure of BT–BNT–xBMT ceramics as shown in figure 5.1(b). In the compositions,  $0.00 \leq x \leq 0.08$ , the crystal structure has a tetragonal symmetry, identified by a splitting of the (002) and (200) peaks. At the higher BMT content of  $x = 0.1$ , the doublet of (002) and (200) peaks become a single peak of (200) and the (111) peak still exhibits a single peak. These results indicated that the crystal structure changed to a pseudocubic symmetry.

The average ionic radius of A – site and B – site, calculated lattice parameters, the tetragonality  $c/a$  ratio and tolerance factor of each composition are listed in Table 5.1. The tetragonality  $c/a$  ratio is the important factor representing the lattice distortion of the tetragonal symmetry. It is seen that the  $c/a$  ratio decreases significantly with increasing BMT content. The ionic radii of  $\text{Bi}^{3+}$  (CN = 12, 1.40 Å) are smaller than the ionic radii of  $\text{Ba}^{2+}$  (CN = 12, 1.61 Å) resulting in the decreasing of average ionic radii at A-site [12]. Also, the substitution of  $\text{Ti}^{4+}$  ions (CN = 6, 0.605 Å) by  $\text{Mg}^{2+}$  (CN = 6, 0.72 Å) results in the increasing of average ionic radii at B-site as shown in Table 5.1. Then, it is reasonable to assume that the substitution of BMT into BT–BNT leads to the distortion and deformation of tetragonal structure. Furthermore, the tolerance factor ( $t$ ) is important factor that reflecting the perovskite structure distortion, rotation and tilt of the  $\text{BO}_6$  octahedra [13]. Generally, the perovskite structure is stable in the range of  $0.880 < t < 1.090$  region [14] and the symmetry is higher as the  $t$  value is approach to 1. It is also noticed that the  $t$  for BT–BNT–xBMT ceramics tends to decrease with increasing BMT which corresponds well with the phase transition from tetragonal to pseudocubic symmetry.

Based on the XRD data, it could be said that the combination between BT–BNT and BMT could form completely crystalline solid solution of perovskite structure but the existence of BMT caused the tetragonality of BT–BNT decrease.

Figure 5.2 Relative permittivity ( $\epsilon_r$ ) and dielectric loss ( $\tan\delta$ ) as a temperature dependence of BT-BNT- $x$ BMT ceramics with the composition  $0.00 \leq x \leq 0.10$ .

Figure 5.2 illustrates the temperature dependence of the relative permittivity ( $\epsilon_r$ ) and dielectric loss ( $\tan\delta$ ) of BT-BNT- $x$ BMT ceramics measured at various frequencies between 1 and 100 kHz. Regarding the composition,  $x = 0.00$ , the relative permittivity of 0.9BT-0.1BNT increased slowly until the temperature approached transition temperature, then it abruptly increased and passed through a maximum of about 178°C. This discontinuity of dielectric constant at phase transition is characteristic of the first order phase transition [15] and occurs from the change of the tetragonal ferroelectric (FE) phase into the cubic paraelectric (PE) phase, in agreement with previous reports [2]. The relative permittivity curves at the compositions,  $0.02 \leq x \leq 0.10$ , showed only one phase transition. The composition,  $x = 0.02$ , showed a

broadening dielectric peak which much like the characteristic of relaxor ferroelectric, however the position of the peaks keep unchanged at various applied frequency. At higher composition,  $0.04 \leq x \leq 0.10$ , the diffuse phase transition behaviour with broad maximum and frequency dispersion became more self-evident when BMT concentration increased. Also, the transition temperature is dependent of frequency and increases with increasing frequency. These results indicated that BT-BNT-xBMT progressively change from normal ferroelectric to relaxor ferroelectric when BMT concentration increases. This phenomenon of BT-BNT-xBMT system resulted from the substitutions of  $\text{Bi}^{3+}$  ions for  $\text{Na}^+$  ions and  $\text{Mg}^{2+}$  ions for  $\text{Ti}^{4+}$ , which distort the unit cell and change dipole moment. For complex perovskite compound, the more cations occupy the equivalent crystallographic site of A or B, the more the chemical fluctuation and structural disorder in arrangement of cations are inhomogeneous at the nanometre scale, then the relaxation characteristic becomes more distinctly [16, 17].

In order to further characterize the relaxor behavior, a modified Curie – Weiss law in equation (1) was used for description a broad relative permittivity and diffuseness of phase transition [18, 19].

$$\frac{\varepsilon_m}{\varepsilon} = 1 + \frac{(T-T_m)^\gamma}{2\delta_\gamma^2} \quad (5.1)$$

Where,  $\varepsilon_m$  is the maximum value of relative permittivity and  $T_m$  is the temperature of dielectric maximum. The  $\gamma$  value expresses the degree of dielectric relaxation in relaxor ferroelectric material which this value is in the range of  $1 \leq \gamma \leq 2$ . When  $\gamma$  value is equal 1, Eq. (1) becomes the classic Curie Weiss law valid in the case of normal ferroelectric. When  $\gamma$  value is equal 5.1, the ideal relaxor behavior with quadratic dependence is described. The parameter  $\delta_\gamma$  is the diffuse parameter which can be used to determine the degree of diffuseness in the phase transition. The  $\delta_\gamma$  value can be observed from the slope of  $\varepsilon'_m/\varepsilon'$  versus  $(T - T_m)^2$ , which should be linear. Plot of  $\ln\left(\frac{1}{\varepsilon} - \frac{1}{\varepsilon_m}\right)$  as function of  $\ln(T - T_m)$  at 100 kHz of BT-BNT-xBMT ceramics are displayed in figure 5.3. By plotting  $\ln\left(\frac{1}{\varepsilon} - \frac{1}{\varepsilon_m}\right)$  versus  $\ln(T - T_m)$ , the  $\gamma$  value can be determined directly from the gradient. The  $\gamma$  and  $\delta_\gamma$  values are determined and shown in Table 5.2. It is clearly seen that both  $\delta_\gamma$  and  $\gamma$  values tend to increase with increasing

of the BMT content, confirming the relaxor behavior in these solid solution. Based on the dielectric data, a slim P-E hysteresis loop in BT-BNT-xBMT ceramic at high BMT content is expected to observe at room temperature.

Figure 5.3 The relative plot between  $\ln\left(\frac{1}{\varepsilon} - \frac{1}{\varepsilon_m}\right)$  versus  $\ln(T - T_m)$

Curie temperature and maximum relative permittivity ( $\varepsilon_{r \max}$ ) at 100 kHz of BT-BNT-xBMT ceramics are determined and plotted as a function of composition in figure 5.4(a). It was observed that Curie temperature decreased rapidly with further increase of BMT. As the previous works have reported that the rapidly decrease in transition can be caused by valence mismatch [20, 21]. In BT-BNT-xBMT system, the differences in valence of ions at A-site ( $\text{Ba}^{2+}$ ,  $\text{Na}^+$ ,  $\text{Bi}^{3+}$ ) and B-site ( $\text{Mg}^{2+}$ ,  $\text{Ti}^{4+}$ ) might be result in valence mismatch, thus Curie temperature decrease with increasing BMT content. Similar behavior is also observed for the substitution of BMT in KNN structure [22]. Moreover, the maximum relative permittivity ( $\varepsilon_{r \max}$ ) of BT-BNT-xBMT ceramics tends to decrease with increasing BMT concentration. However, at room temperature the relative permittivity ( $\varepsilon_{r \text{ room}}$ ) tends to abruptly increase with increasing BMT,

excepting the composition,  $x = 0.10$ . While, dielectric loss ( $\tan\delta$ ) tend to gradually increase with BMT increase as shown in figure 5.4(b). The smooth increase of  $\epsilon_{r\ room}$  for the compositions,  $0.02 \leq x \leq 0.08$ , might be attributed to the decreasing of Curie temperature to room temperature. While, the  $\epsilon_{r\ room}$  of composition,  $x = 0.10$  is decrease might be the Curie temperature being below room temperature.

Figure 5.4 (a) The relative plot between Curie temperature and maximum relative permittivity( $\epsilon_{r\ max}$ ) as a function of composition(x) (b) The relative plot between relative permittivity at room temperature( $\epsilon_{r\ room}$ ) and dielectric loss ( $\tan\delta$ ) as a function of composition(x).

The composition dependence of polarization-electric field (P-E) hysteresis loops for BT-BNT-xBMT system was measured at room temperature with electric field of 60 kV/cm, as shown in figure 5.5. It is evident that all ceramics display the saturated P-E hysteresis loops. For 0.9BT-0.1BNT, a shape of hysteresis loop displays typically normal ferroelectric behavior with remanent polarization ( $P_r$ ) and coercive field ( $E_c$ ) of 15.52  $\mu\text{C}/\text{cm}^2$  and 29.47 kV/cm, respectively, which in good agreement with previous work [2]. Normal ferroelectric contains a long-range interaction between dipoles in the ferroelectric micro-domain state, giving a typical square hysteresis loops with high  $P_r$  and  $E_c$ . As expected for BT-BNT-xBMT ceramics, the substitution of BMT has significantly effect on the hysteresis loops shape and polarization and coercive field values. The more BMT concentration increases, the more the hysteresis loop shape becomes slim, identified the gradually drop of  $P_r$ ,  $P_s$  and  $E_c$  values as summarized in Table 5.2. This result suggests that the long-range order of polarization in ferroelectric micro-domain was significantly broken down to polar nano-regions by adding BMT. Then, at high content of BMT, normal ferroelectric BT-BNT-xBMT ceramics become relaxor-like behavior exhibiting a slim P-E hysteresis loop with low  $P_r$  and  $E_c$ . For low content of BMT, the decreasing of  $P_r$  and  $E_c$  might be due to an easier of domain switching and domain wall motions [23] as well as tetragonality decreasing of crystal structure in this system [24]. The plots of  $P_r$  and  $E_c$  values against composition are given in figure 5.6. Again, a clearly smooth trend of decrease was seen in  $P_r$  and  $E_c$  with respect to BMT content, confirming the completely solid solution formation in BT-BNT-xBMT system.

Figure 5.5 The relative plot of polarization ( $\mu\text{C}/\text{cm}^2$ ) with electric field (kV/cm) of BT-BNT-xBMT ( $x = 0.00-0.10$ ) ceramics.

Figure 5.6 The composition ( $x$ ) dependence of Remanent polarization ( $P_r$ ,  $\mu\text{C}/\text{cm}^2$ ) and coercive field ( $E_c$ , kV/cm) in BT-BNT-xBMT ceramics.

To confirm the changes in hysteresis behavior, the empirical relationship between  $P_r$ ,  $P_s$  and polarization at fields above the  $E_c$  proposed by Haertling and Zimmer was used for calculated the squareness of hysteresis loop [25]

$$R_{sq} = \frac{P_r}{P_s} + \frac{P_{1.1E_c}}{P_r} \quad (5.2)$$

where,  $R_{sq}$ ,  $P_r$  and  $P_s$  are squareness of hysteresis loop, remanent polarization and saturation polarization, respectively.  $P_{1.1E_c}$  is the polarization at an electric field equal to 1.1 times the coercive field ( $E_c$ ). The squareness parameter reflects the quantification of changes P-E hysteresis loops. For an ideal P-E hysteresis loop, the  $R_{sq}$  is equal to 5.2. The calculated  $R_{sq}$  for all ceramics is listed in Table 5.2. It is clearly found that, as BMT content increase, the  $R_{sq}$  parameter decreases from 1.56 to 0.33 which implies that P – E hysteresis loop becomes more slanted. On the other words, the P – E loops changes from normal ferroelectric to relaxor behavior with increasing BMT concentration which is consistent with the dielectric result.

Combined with the ferroelectric, the dielectric and XRD results of BT–BNT–xBMT ceramic, all of changes such as the transformation of crystal structure, the decreasing of transition temperature and remanent polarization and ferroelectric– relaxor ferroelectric phase transition are so smooth. Therefore, it could be said that BT–BNT and BMT can completely form solid solution throughout the whole composition range.

Figure 5.7 illustrates the unipolar strain curves of BT–BNT–xBMT ceramics measured at room temperature with an external electric field of 60 kV/cm. It is clearly found the decreasing of unipolar strain of BT–BNT–xBMT ceramics from 0.2% to 0.09% when the composition of  $x$  was increased from 0.00 to 0.10. The normalized strain ( $d_{33}^*$ ) value of BT-BNT-XBMT ceramics was calculated from the  $S_{max}/E_{max}$  ratio for each composition. The composition dependence of normalized strain tends to decrease from 328 pC/N to 153 pC/N when composition of BMT increases, as represented in figure 5.8. This result has caused the approaching to the relaxor-like behavior with increasing of BMT [26]. The composition dependence of the level of induce strain is similar to result observation of BT–Bi( $Ni_{1/2}Ti_{1/2}$ )O<sub>3</sub> system [27].

Figure 5.7 The relative plot of unipolar strain (%) as a function of electric field (kV/cm) in BT-BNT-xBMT ( $x = 0.00 - 0.10$ ) ceramics.

Figure 5.8 Normalized strain ( $d_{33}^*$  (pm/V)) value of BT-BNT-xBMT ceramics with the composition  $0.00 \leq x \leq 0.10$ .

Figure 5.9 displays SEM micrograph of the sintered surfaces of BT–BNT–xBMT ceramics at  $x = 0.00, 0.02, 0.04$  and  $0.10$ . The substitution of BMT directly effects on the average grain size of BT–BNT–xBMT ceramics. For the composition  $x = 0.00$ , the grain morphology shows and the average grain size is about  $1.01 \pm 0.14 \mu\text{m}$ . Homogeneous and uniformity feature microstructures were observed in the composition  $x = 0.00$ . The wide grain size distributions was observed in the composition  $x = 0.02$  and  $0.04$ . For the composition  $x = 0.10$ , more disorderly and unsystematic shaped grains are observed. A dramatic grain growth inhibition was founded with increasing BMT composition. The average grain size decreased significantly with increasing the composition  $x$ . The average grain size are about  $0.72 \pm 0.09 \mu\text{m}$ ,  $0.54 \pm 0.09 \mu\text{m}$ , and  $0.49 \pm 0.07 \mu\text{m}$  for the composition  $x = 0.02, 0.04$  and  $0.10$  respectively. This should be attributed to the effects arisen from the donor–type nature of BMT on inhibiting the grain growth [22]. The decreasing in piezoelectric properties in BNT–BT–xBMT system may be attributed to the inhibiting of the grain growth coursed by substitution of BMT in the BNT–BT system. The detailed mechanisms of the diminution in piezoelectric properties of BT–BNT–xBMT system are unclear and demands further study.

**Figure 5.9** SEM micrographs of BT–BNT–xBMT ceramics with various compositions (a)  $x = 0.00$ , (b)  $x = 0.02$ , (c)  $x = 0.04$ , and (d)  $x = 0.10$ .

## 5.4 Conclusion

Lead free  $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  (BT-BNT-xBMT;  $x = 0.00 - 0.10$ ) piezoelectric ceramics were synthesized successfully by the solid state reaction. The crystal structure of BT-BNT-xBMT solid solution transforms from tetragonal to pseudocubic symmetry with increasing of BMT content. Combined with the ferroelectric and the dielectric results of BT-BNT-xBMT ceramic, phase transition of ceramics gradually changed from ferroelectric to relaxor-like behavior as BMT content increased. Also, BT-BNT and BMT can completely form solid solution throughout the whole composition range.

## CHAPTER 6

# CONCLUSIONS AND SUGGESTION FOR FURTHER WORK

### 6.1 Conclusions

The barium titanium-based ternary system in two systems:  $\text{BaTiO}_3\text{-SrTiO}_3\text{-}y\text{BaSnO}_3$  and  $\text{BaTiO}_3\text{-Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3\text{-Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  ceramics were selected, to design the multi-phase composition. All ceramics samples in both systems were prepared by conventional solid state method. The structure-properties relationship was explored.

The first ternary system was  $(0.975-y)\text{BaTiO}_3\text{-}0.025\text{SrTiO}_3\text{-}y\text{BaSnO}_3$ , where  $y = 0.00, 0.02, 0.04, 0.06, 0.08$  and  $0.10$ . The effect of Sn substitution on the ferroelectric phase transition and piezoelectric properties was explored to achieve high-performance piezoelectric properties. All of the ceramics exhibited pure perovskite structures. The coexistent tetragonal and orthorhombic phases were exhibited at the composition,  $y = 0.04$ , and showed an outstanding dielectric and piezoelectric properties, relative permittivity ( $\epsilon_r$ ) of 11,500 and piezoelectric coefficient ( $d_{33}$ ) of 449 pC/N. An outstanding reversible strain of about 0.12%, with a normalized piezoelectric coefficient ( $S_{\text{max}}/E_{\text{max}}$ ) of 1,280 pm/V at a low electric field (10 kV/cm), was observed clearly at the composition of the coexistent phase. This result indicated that the  $(0.975-y)\text{BaTiO}_3\text{-}0.025\text{SrTiO}_3\text{-}y\text{BaSnO}_3$  ceramics are one promising candidate system for lead-free piezoelectric materials.

The second system was  $0.9\text{BaTiO}_3\text{-}(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3\text{-}x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  system, where  $x = 0.00, 0.02, 0.04, 0.06, 0.08, 0.10$ . The effect of BMT on crystal structure and electrical property of BT-BNT ceramics was investigated as a function of composition,  $x$ . The crystal structure of solid solution BT-BNT-xBMT, where  $x = 0.00 - 0.10$ , successively transforms from tetragonal to pseudocubic symmetry, with increased BMT concentration. Temperature dependence of dielectric constant ( $\epsilon_r$ ) and dielectric loss ( $\tan\delta$ ) for BT-BNT-xBMT at various frequencies showed that phase transition of ceramics changed from ferroelectric to relaxor-like behavior as BMT content increased. Furthermore, remanent polarization ( $P_r$ ), coercive field ( $E_c$ ) and the

normalized strain ( $d_{33}^*$ ) of BT-BNT-BMT ceramics tend to decrease with increasing BMT concentration.

## 6.2 Suggestions for further work

In part of structural characterization in X-ray diffraction result, it can be seen that the diffraction peak of coexisting orthorhombic and tetragonal phases is not clearly because of the relatively low resolution of the traditional X-ray diffractometer. In the future work, we suggest the following X-ray diffractometer from synchrotron radiation that has better line resolution to clarify the structure of ceramics.

## ABSTRACT

Design of the polymorphic phase composition in the  $(0.975-y)\text{BaTiO}_3-0.025\text{SrTiO}_3-y\text{BaSnO}_3$ ; BT-ST- $y\text{BSn}$  ternary system was based on the ferroelectric phase diagram. The dense ceramic of BT-ST- $y\text{BSn}$ , with  $y = 0.00, 0.02, 0.04, 0.06, 0.08$  and  $0.10$  compositions, was fabricated successfully via the solid-state reaction method. The effect of Sn substitution on the ferroelectric phase transition and piezoelectric properties was explored in order to achieve high-performance piezoelectric properties. All of the ceramics exhibited pure perovskite structures. Orthorhombic to tetragonal phase transition was evidenced clearly as a function of Sn content. The orthorhombic to tetragonal phase transition shifted close to ambient temperature by increasing the Sn content. The coexistent tetragonal and orthorhombic phases were exhibited at the composition,  $y = 0.04$ , and showed outstanding dielectric and piezoelectric properties, maximum relative permittivity ( $\epsilon_{r \text{ max}}$ ) of 11500 and piezoelectric coefficient ( $d_{33}$ ) of 450 pC/N. An outstanding reversible strain of about 0.12%, with a normalized piezoelectric coefficient ( $S_{\text{max}}/E_{\text{max}}$ ) of 1280 pm/V at a low electric field (10 kV/cm), was observed clearly at the composition of the coexistent phase. The BT-ST- $y\text{BSn}$  ceramics are the most promising candidate for lead-free piezoelectric materials.

## Introduction

Lead-based piezoelectric ceramics such as lead zirconate titanate [ $\text{Pb}(\text{Zr}_{1-x}\text{Ti}_x)\text{O}_3$ ; PZT] have been used most widely in actuator and sensor devices, due to their excellent piezoelectric properties [1]. Nevertheless, PZT ceramics are environmentally unfriendly and dangerous to human health, due to the toxicity of lead in fabrication processing [2, 3]. Therefore, attention has been drawn to lead-free piezoelectric materials with a performance comparable to that in lead-based materials. Consequently, in recent years diverse systems have been explored, including bismuth-alkaline metal titanates and niobates, and especially  $\text{BaTiO}_3$ ; BT solid solution [2–5].

Ferroelectric behavior was discovered in Barium titanate ( $\text{BaTiO}_3$ ; BT) by Wul and Goldman in 1946 [6], which led to the widespread use of BT in capacitors and electromechanical devices [6, 7]. BT has a tetragonal perovskite structure at room temperature, and pure BT exhibits a piezoelectric constant ( $d_{33}$ ) of about 191 pC/N [8] that is relatively low when compared to PZT-based ( $d_{33} = 300\text{--}600$  pC/N) [8]. Therefore, BT has been modified by doping with A and/or B site substitutions [9–11]. The binary system of  $\text{BaTiO}_3\text{--BaSnO}_3$ ; BT-BSn recently showed high dielectric permittivity ( $\epsilon_r$ )  $\sim 75000$  and excellent piezoelectric coefficient ( $d_{33}$ )  $\sim 697$  pC/N at the quasi-quadruple point, which exhibited coexistent Cubic–Tetragonal–Orthorhombic–Rhombohedral phases in BT-BSn [12]. Wang et al. [13] reported a high electrostriction strain of  $\sim 0.22\%$  in the binary systems of  $\text{BaTiO}_3\text{--CaTiO}_3$ ; BT-CT. Excellent piezoelectric properties also were obtained in the coexistent phase composition in the  $\text{BaTiO}_3\text{--BaZrO}_3\text{--CaTiO}_3$ ; BT-BZ-CT and  $\text{BaTiO}_3\text{--BaZrO}_3\text{--CaTiO}_3$ ; BT-BS-CT system [9, 14]. The  $(\text{Ba}_{1-x}\text{Ca}_x)(\text{Ti}_{0.92}\text{Sn}_{0.08})\text{O}_3$  ceramics recently displayed high  $d_{33} = 568$  pC/N,  $k_p = 47.7\%$ ,  $\epsilon_r = 23,000$  and normalized strain ( $dS/dE$ ) = 1013 pm/V at the orthorhombic/tetragonal coexistent phase composition [15]. The coexistent phase composition in the Sn dope BT-CT system also exhibited ultra-high  $d_{33}$  (670 pC/N) and electrostrain (0.061%) [16]. Li et al. [17] recently reported a high piezoelectric coefficient ( $d_{33}$ ) of about 380 pC/N and  $k_p$  of about 38% in the Sr dope  $\text{Ba}(\text{Zr,Ti})\text{O}_3$ ; BZT system. The Sr substitute BZT, not only enhanced piezoelectric properties by shifting the ferroelectric phase transition close to room temperature, but also decreased the sintering temperature of the ceramic.

In order to find new BT-based ceramics with excellent piezoelectric properties, Sn cation was selected to substitute the Sr-doped  $\text{BaTiO}_3$  in this work. Sr-doped BT was used as a base composition, due to Sr being able to enhance piezoelectric properties and slightly decrease the sintering temperature of the ceramic. Systematic study of how the Sn substitution affects crystal structure, and dielectric and piezoelectric behavior of  $(0.975-y)\text{BaTiO}_3\text{--}0.025\text{SrTiO}_3\text{--}y\text{BaSnO}_3$ ; BT-ST- $y$ BSn ceramics, is still rare. The BT-ST- $y$ BSn ceramic, with  $y = 0.00, 0.02, 0.04, 0.06, 0.08$  and 0.10 compositions, is designated in this study as a lead-free composition that explores the compositional dependence of structure and piezoelectric behavior in Sn content. The development of piezoelectric properties by optimizing Sn content in BT-ST- $y$ BSn ceramics has been established.

## Experimental procedure

The  $(0.975-y)\text{BaTiO}_3\text{--}0.025\text{SrTiO}_3\text{--}y\text{BaSnO}_3$ ; BT-ST- $y$ BSn ceramic, with  $y = 0.00, 0.02, 0.04, 0.06, 0.08$  and 0.10 compositions, was fabricated via the solid-state reaction technique. The metal carbonate and oxide powder of  $\text{BaCO}_3$  (99.9%, Inframal Advance Materials),  $\text{SrCO}_3$  (99.5%, Inframal Advance Materials),  $\text{TiO}_2$  (99.9%, Sigma-Aldrich) and  $\text{SnO}_2$  (99.9%, Inframal Advance Materials) were used as raw materials. The stoichiometric amount of starting materials was mixed in ethanol with yttrium-stabilized zirconia in the first step and then vibro-milled for 6 h. The mixtures were dried and calcined at temperatures between 1200 and 1300 °C for 4 h, with a heating/cooling rate of 5 °C/min. The calcined powders were ground and sieved. Finally, the calcined powders were pressed into pellets of 10–20 mm diameter and a thickness of about 1–1.5 mm, using 5 wt% polyvinyl alcohol (PVA) as a binder. The pellets were sintered at between 1375 and 1450 °C for 4 h with a heating/cooling rate of 5 °C/min. Ceramics with more than 94% theoretical density were selected for investigating electrical properties. The crystal structure of ceramics was carried out with X-ray diffraction (Bruker-AXS D 8 Advance) using  $\text{CuK}_\alpha$  radiation in the  $2\theta$  scan range of 20°–80°. In order to support crystal structure identification of the ceramics, Raman spectra were measured in the 100–1000  $\text{cm}^{-1}$  wave number range with a Thermo Scientific DXR Raman microscope, using the 532 nm exciting line of

**Figure 1** **a** X-ray diffraction patterns of BT-ST- $y$ BSn ceramic between the  $2\theta$  range of  $20^\circ$ – $80^\circ$ , **b** expanded range of  $38^\circ$ – $40^\circ$ , **c** expanded range of  $44^\circ$ – $46^\circ$  and **d** expanded range of  $55^\circ$ – $57^\circ$ .

a He–Ne laser. In order to obtain electrical measurement, both sides of the samples were polished and paralleled for electrical measurements. Then, the pellets were coated on both surfaces with silver electrodes (C1000, Heraeus) and heated at  $750^\circ\text{C}$  for 20 min, with a heating/cooling rate of  $5^\circ\text{C}/\text{min}$ . The frequency (1, 10, 100 kHz) and temperature (room temperature to  $160^\circ\text{C}$ ) dependence of relative permittivity ( $\epsilon_r$ ) and dielectric loss ( $\tan \delta$ ) were obtained by using an LCR analyzer (HP4284A, Hewlett-Packard, Palo Alto, CA, USA). Ferroelectric hysteresis loops were determined at room temperature by using a ferroelectric tester (RT66A, Radiant Technologies, Inc.), and the strain-electric field ( $S$ – $E$ ) loop was measured by unipolar driving at 4 Hz using an MTI-2100 Fotonic sensor combined with a ferroelectric tester. The pellets of 10 mm diameter and 0.6 mm thickness were poled under a DC field at 35–40 kV/cm for 30 min at room temperature and aged for 24 h before piezoelectric measurements. The piezoelectric coefficient,  $d_{33}$ , was characterized using a quasi-static  $d_{33\text{ m}}$  (YE2730A, APC International Ltd.).

## Results and discussion

The characteristics of crystal structured ceramics were examined by X-ray diffraction (XRD). XRD patterns of the BT-ST- $y$ BSn system, with compositions of  $y = 0.00, 0.02, 0.04, 0.06, 0.08$  and  $0.10$ , are

shown in Fig. 1a–d. All of the samples demonstrated a single phase with the perovskite structure, and the secondary or impure phase was not observed in the XRD patterns, which indicates that both Sr and Sn ions are fully diffused into the  $\text{BaTiO}_3$  lattice to form solid solution. The crystal structure of BT-ST- $y$ BSn at the compositions,  $0.00 \leq y \leq 0.02$ , has a tetragonal symmetry, identified by a single peak at  $2\theta$  of  $38.7^\circ$  (Fig. 1b) and splitting of (002) and (200) peaks at  $2\theta$  of  $44.8^\circ$ – $45.6^\circ$  (Fig. 1c). At higher compositions of  $0.06 \leq y \leq 0.10$ , the XRD pattern exhibits splitting of two peaks [(102)/(120)] at around  $38^\circ$ – $39.5^\circ$  and splitting of three peaks [(113)/(131)/(202)] at around  $55.8^\circ$ – $56.3^\circ$ , which indicates an orthorhombic symmetry (Fig. 1d). Therefore, the results indicated that the crystal structure changed from tetragonal to orthorhombic phase with increasing Sn content. Meanwhile, it is anticipated that the tetragonal and orthorhombic phases for  $y = 0.04$  coexist, which is confirmed by dielectric and piezoelectric measurements. It is seen clearly that the diffraction pattern of all compositions shifts gradually to low angles with increasing Sn content, which should induce expansion of the host lattice. Lattice parameter ( $\text{\AA}$ ) and unit cell volume ( $\text{\AA}^3$ ) were calculated and plotted as a function of Sn content, as shown in Fig. 2a, b. Regarding the compositions,  $0.00 \leq y \leq 0.02$ , with tetragonal symmetry, the unit cell  $a$  and  $c$  increase slightly with increasing Sn content, which corresponds with increased unit cell volume. The

**Figure 2** Relative plot between the **a** lattice parameter (Å), and **b** cell volume (Å<sup>3</sup>) and composition  $y$  in BT-ST- $y$ BSn ceramic.

ostensibly discontinuous changes are noticed at  $0.02 < y < 0.06$  when the tetragonal and orthorhombic phases coexist. The orthorhombic lattice parameters ( $a$ ,  $b$  and  $c$ ) and unit cell volume slightly increase for the compositions,  $0.06 \leq y \leq 0.10$ . This is consistent with the result reported by Zhu et al. [16]. The increase in the lattice parameter is caused mainly by the majority of Sn ions substitute  $Ti^{4+}$  ions the B site of the perovskite structure with  $Sn^{4+}$  state. However, it should be noted that the valency of the Sn ion is very sensitive and allowed to adapt to a divalent, trivalent and tetravalent state in oxide ceramics [18]. Suzuki et al. [19] reported that under sintering conditions of reducing atmosphere, the Sn ions can substitute  $Ba^{2+}$  ions at the A-site of the perovskite structure with  $Sn^{2+}$  state. The oxidation states of the Sn ion in BT-ST- $y$ BSn ceramics must be considered for future investigation. Dependence on the composition of Raman spectra for BT-ST- $y$ BSn systems was investigated at room temperature in the frequency range of 100–1000  $cm^{-1}$ , as shown in Fig. 3a–d. The ferroelectric phase with tetragonal symmetry

**Figure 3** **a** Raman spectra of BT-ST- $y$ BSn ceramic at room temperature with the compositions,  $0.00 \leq y \leq 0.10$ , in the wave number range from 100 to 1000  $cm^{-1}$ , **b** enlarged Raman shift range from 100 to 290  $cm^{-1}$ , **c** enlarged Raman shift range from 200 to 310  $cm^{-1}$  and **d** the relative plot between wave number  $cm^{-1}$  and composition  $y$ .

corresponds with group theory analysis in normal optical mode, with each  $F_{1u}$  mode transforming into  $A_1$  and  $E$  modes, whereas the  $F_{2u}$  mode gives rise to  $B_1$  (silent) and  $E$  modes. All spectra generally display Raman-active modes of ferroelectric material. The interference dips at around 180  $cm^{-1}$ , due to antiresonance between sharp  $A_1(TO_1)$  and broad  $A_1(TO_2)$  modes, such as a broad peak of  $A_1(TO_2)$  mode near 257  $cm^{-1}$ ; sharp peak of  $E(TO_2)$  mode at 295  $cm^{-1}$ ; broad peak of  $A_1(TO_3)$  and  $E(TO)$  mode at around 515  $cm^{-1}$ , which is a bending and stretching vibration of symmetric Ti–O in  $[TiO_6]^{2-}$ ; and a broad peak of  $A_1(LO_3)/E(LO_3)$  mode at around 712  $cm^{-1}$  [20]. Therefore, Raman spectra of all compositions are observed at a broad peak of  $A_1(TO_2)$ ,  $E(TO_2)$ ,  $A_1(TO_3)/E(TO)$ ,  $A_1(LO_3)/E(LO_3)$  and interference

**Figure 4** Relative permittivity ( $\epsilon_r$ ) and dielectric loss ( $\tan \delta$ ) as temperature dependent BT-ST-yBSn ceramic with compositions,  $0.00 \leq y \leq 0.10$ .

dip mode (Fig. 3a), which indicates that all compositions exhibit ferroelectric phase. The signature Raman mode of tetragonal phase for BT is generally a broad  $A_1(\text{TO}_2)$  mode, sharp  $E(\text{TO}_2)$  mode, broad  $A_1(\text{TO}_3)/E(\text{TO})$  mode, swelling  $A_1(\text{LO}_2)/E(\text{LO})$  mode and broad  $A_1(\text{LO}_3)/E(\text{LO}_3)$  mode [21]. Also, the mode of orthorhombic phase is a broad  $A_1(\text{TO}_1)$ ,  $A_1(\text{TO}_2)$ ,  $A_1(\text{TO}_3)/E(\text{TO})$  and  $A_1(\text{LO}_3)/E(\text{LO}_3)$  peak and sharp  $E(\text{TO}_2)$  peak [21]. In the compositions,  $0.00 \leq y \leq 0.02$ , all of the Raman patterns show  $A_1(\text{TO}_2)$ ,  $E(\text{TO}_2)$ ,  $A_1(\text{LO}_2)/E(\text{LO})$ ,  $A_1(\text{TO}_3)/E(\text{TO})$  and  $A_1(\text{LO}_3)/E(\text{LO}_3)$  at around 260, 303, 472, 517 and 720  $\text{cm}^{-1}$ , respectively, which indicates a ferroelectric tetragonal phase. At the higher compositions,  $0.04 \leq y \leq 0.10$ , the

$A_1(\text{TO}_1)$  mode appeared gradually at 190  $\text{cm}^{-1}$  and  $A_1(\text{LO}_2)/E(\text{LO})$  mode at 472  $\text{cm}^{-1}$ , but both were absent in the Raman spectrum. Therefore, the compositions,  $0.06 \leq y \leq 0.10$ , were considered as a signature of the ferroelectric orthorhombic phase by the presence of  $A_1(\text{TO}_1)$ ,  $A_1(\text{TO}_2)$ ,  $E(\text{TO}_2)$ ,  $A_1(\text{TO}_3)/E(\text{TO})$  and  $A_1(\text{LO}_3)/E(\text{LO}_3)$  mode near 190, 222, 301, 514 and 716  $\text{cm}^{-1}$ , respectively. A weak  $A_1(\text{TO}_1)$ ,  $A_1(\text{TO}_2)$ ,  $E(\text{TO}_2)$ ,  $A_1(\text{TO}_3)/E(\text{TO})$  and  $A_1(\text{LO}_3)/E(\text{LO}_3)$  peak at the composition,  $y = 0.04$ , showed coexistence of the ferroelectric tetragonal and orthorhombic phase. These results identified that the phase transition changed from tetragonal to orthorhombic phase, which corresponds well with the XRD pattern.

**Figure 5** Relative plot between transition temperature (T<sub>m</sub>) and maximum relative permittivity (ε<sub>r max</sub>) at 1 kHz of BT-ST-yBSn ceramic as a function of composition y.

**Figure 6** Relative plot between ln(1/ε - 1/ε<sub>m</sub>) and ln(T - T<sub>m</sub>).

Figure 4 presents the temperature dependence of relative permittivity (ε<sub>r</sub>) and dielectric loss (tan δ) of BT-ST-yBSn systems with y = 0.00, 0.02, 0.04, 0.06, 0.08 and 0.10 compositions at frequencies 1, 10 and

100 kHz. The relative permittivity curves for the composition, y = 0.00 and 0.02, exhibit one sharp peak at 110 and 97 °C, respectively, with this transition being related to the transition from tetragonal (P4 mm) ferroelectric to cubic (Pm3m) paraelectric phase. Nevertheless, the relative permittivity curves for the compositions, 0.04 ≤ y ≤ 0.08, presented two anomalous peaks. A higher temperature was associated with the ferro-to-paraelectric phase transition, while a lower temperature suggested the phase transition from orthorhombic to tetragonal phase. The O-T phase transition temperature shifted slightly with increasing Sn content to a high temperature from 32 °C for y = 0.04–41 °C for y = 0.08. Furthermore, the transition temperature decreases with increasing Sn content (Fig. 5). The temperature range width of the tetragonal phase decreases continuously with increasing Sn content. The permittivity at room temperature is seen to increase continuously from y = 0.00–0.04 with increasing Sn content. This result is due to the shift of O-T phase transition temperature that is close to room temperature. It is known that the relative permittivity of a normal ferroelectric phase, which is above the maximum relative permittivity temperature, can be described by the Curie-Weiss law [7, 22];

$$\frac{1}{\epsilon_r} = \frac{C}{T - T_0}, \quad (T > T_c) \tag{1}$$

where T<sub>0</sub> is the Curie-Weiss temperature and C is the Curie-Weiss constant. The relative permittivity of pure BT obeys the Curie-Weiss law, which is T<sub>0</sub> ~ 383 K and C ~ 1.56 × 10<sup>5</sup> K [14]. However, further characterization of broad relative permittivity and diffuseness of the phase transition followed a modified Curie-Weiss law, as described below [23, 24]:

**Figure 7** a Plot between polarization ( $\mu\text{C}/\text{cm}^2$ ) and electric field (kV/cm) as a function of composition  $y$ , and b the plot of remanent polarization ( $\mu\text{C}/\text{cm}^2$ ) and coercive field (kV/cm) value as a function of composition  $y$ .

$$\frac{\epsilon_m}{\epsilon} = 1 + \frac{(T - T_m)^\gamma}{2^2}, \quad (\text{at } T > T_m), \quad (2)$$

where  $\gamma$  is constant and  $\epsilon_m$  is the maximum value of relative permittivity at phase transition temperature ( $T_m$ ). The parameter  $\gamma$  expresses information on the character of the phase transition, and when  $\gamma = 1$ , the equation follows the Curie–Weiss law, which indicates normal ferroelectrics, while  $\gamma = 2$  describes a complete diffuse phase transition. The  $\delta$  value can be applied to gauge the degree of diffuseness in the phase transition. Figure 6 illustrates the plot of  $\ln\left(\frac{1}{\epsilon} - \frac{1}{\epsilon_m}\right)$  as a  $\ln(T - T_m)$  function of BT-ST- $y$ BSn systems at 1 kHz. The value of parameter  $\gamma$  and  $\delta$  is presented in Table 1. It can be seen that parameter  $\gamma$  tends to increase from 1.20 to 1.37 with increasing Sn content. The  $\delta$  value has a similar tendency to increase from 12.47 to 13.40 with increasing Sn content, thus confirming that a diffuse phase transition appears in the BT-ST- $y$ BSn system. This result occurs when at least two cations dominate the same

**Figure 8** a Relative plot between unipolar strain (%) and electric field (kV/cm) as a function of composition, and b the plot of normalized strain [ $d_{33}^*$  (pm/V)] and piezoelectric constant [ $d_{33}$  (pC/N)] value as a function of composition  $y$ .

crystallographic site, a or b, which is found in many complex perovskite structures such as lead-free  $\text{BaZrO}_3\text{--CaTiO}_3\text{--BaTiO}_3$  [11],  $\text{K}_{0.5}\text{Na}_{0.5}\text{NbO}_3\text{--LiSbO}_3$  [25] and  $(\text{Ba}_{0.85}\text{Ca}_{0.15})(\text{Zr}_{0.1}\text{Ti}_{0.9})\text{O}_3\text{--Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  [26].

In order to investigate the ferroelectric behavior in BT-ST- $y$ BSn ceramics, the electrical polarization hysteresis loop of each composition was measured at room temperature with an electric field of 60 kV/cm. Figure 7a illustrates the polarization–electric field hysteresis loop for all compositions of  $y$  at a frequency of 4 Hz. All BT-ST- $y$ BSn ceramics with  $y = 0.00\text{--}0.10$  compositions exhibit symmetry in shape and well-saturated hysteresis loops and result in domain switching in an electric field. The plot of  $P_r$  and  $E_c$  value as a function of composition  $y$  is presented in Fig. 7b. It can be seen that the  $P_r$  initially tends to increase from  $12.93 \mu\text{C}/\text{cm}^2$  at  $y = 0.00$  to a maximum value of  $13.14 \mu\text{C}/\text{cm}^2$  at  $y = 0.04$ , and then it decreases gradually from  $10.48 \mu\text{C}/\text{cm}^2$  at  $y = 0.06\text{--}6.95 \mu\text{C}/\text{cm}^2$  at  $y = 0.10$ . In addition, the  $E_c$

values decrease clearly from 7.00 to 3.08 kV/cm with increasing Sn content, as shown in Fig. 7b. The decrease in  $E_c$  indicates that ceramics become “softer” with increasing Sn content, regarding the electric field, because the free energy profile for polarized rotation is flattened anisotropically at the two phases and multiphase coexistence [12, 27]. In order to investigate the changes in hysteresis loop behavior, the empirical relationship between  $P_r$ ,  $P_s$  and polarization at fields above  $E_c$  was proposed by Haertling and Zimmer for calculating squareness of the hysteresis loop as follows [28]:

$$R_{sq} = \frac{P_r}{P_s} + \frac{P_{1.1E_c}}{P_r} \quad (3)$$

where  $R_{sq}$  is the squareness of the hysteresis loop, and  $P_r$  and  $P_s$  are remanent and saturated polarization, respectively.  $P_{1.1E_c}$  is polarization at an increasing electric field of 1.1 times the coercive field ( $E_c$ ). The squareness parameter investigates the quantification of changes in  $P$ - $E$  hysteresis loops. The  $R_{sq}$  is equal to 2 for an ideal  $P$ - $E$  hysteresis loop. The calculated  $R_{sq}$  values of all ceramics are inferred in Table 1. It was found that the  $R_{sq}$  parameter tended to decrease from 0.80 to 0.72 with increasing Sn content, which implies that the  $P$ - $E$  hysteresis loop becomes more slanted. Figure 8a displays the unipolar electric field induced strain curve for the BT-ST- $y$ BSn ceramic, with  $y = 0.00$ – $0.10$  compositions, measured at 10 kV/cm. It can be observed that with increasing Sn content, the unipolar strain increases with increasing  $y$  of up to 0.04 and reaches the maximum electrostrain value of 0.13%. On increasing  $y$  further to 0.1, the unipolar strain decreases to 0.074%. Figure 8b illustrates the direct piezoelectric coefficient ( $d_{33}$ ) and a normalized strain or converse piezoelectric coefficient ( $d_{33}^* = S_{max}/E_{max}$ ) at the electric field of 10 kV/cm as a function of composition. It can be observed that the  $d_{33}^*$  value tends to increase with increasing composition  $y$  and reaches its maximum at about 1280 pm/V at  $y = 0.04$ , before decreasing with increasing composition  $y$ . The  $d_{33}^*$  values also have a similar trend and maximum  $d_{33}$  values of 450 pC/N, as  $y$  increases to 0.04. As a result, ceramic at the composition,  $y = 0.04$ , exhibits the highest normalized strain and piezoelectric constant in the systematic series studied, due to the coexistence of orthorhombic and tetragonal phase near room temperature. The enhanced  $d_{33}$  and  $d_{33}^*$  values are considered to be reasonably consistent with the

multiphase coexistence of the orthorhombic and tetragonal phase that occurs near ambient temperature at  $y = 0.04$ . In the point view of crystallographic symmetry, there are 18 domain orientation states (6 domain states along 100c direction for tetragonal symmetry and 12 along 110c direction for orthorhombic symmetry) near the O-T phase transitions. In general, a large number of thermodynamically equivalent states near O-T phase transitions allow a high degree of ferroelectric dipole alignment. This causes instability, multiple polarization and strain variants, so that the direction of polarization is rotated easily by external stress or the electric field, thus making it much easier for different grains to coordinate in a collective response.

## Conclusion

BT-ST- $y$ BSn ceramic was fabricated by the conventional solid-state reaction method. Raman and XRD study indicates that the orthorhombic and tetragonal phases coexist near ambient temperature at  $y = 0.04$ . Enhanced dielectric, ferroelectric and piezoelectric properties of  $\epsilon_r \text{ max} \sim 11500$ ,  $P_r \sim 13.14 \mu\text{C}/\text{cm}^2$ ,  $d_{33}^* \sim 1280 \text{ pm}/\text{V}$  and  $d_{33} \sim 450 \text{ pC}/\text{N}$  were obtained as samples at  $y = 0.04$ . This observation indicated that the BT-ST- $y$ BSn system is a promising candidate for lead-free piezoelectric ceramics.

*Solid solution of  $0.9\text{BaTiO}_3-(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3-x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  (BT-BNT-xBMT) system, where  $x = 0.00, 0.02, 0.04, 0.06, 0.08, 0.10$ , was synthesized by the solid state reaction. Dense BT-BNT-xBMT ceramics were obtained by sintering at  $1,150-1,250^\circ\text{C}$  for 4 h. The effect of BMT on crystal structure and electrical property of BT-BNT ceramics was investigated as a function of composition,  $x$ , using X-ray diffraction, dielectric spectroscopy, hysteresis and strain measurements. The crystal structure of solid solution BT-BNT-xBMT, where  $x = 0.00-0.10$ , successively transforms from tetragonal to pseudocubic symmetry, with increased BMT concentration. Temperature dependence of dielectric constant ( $\epsilon_r$ ) and dielectric loss ( $\tan\delta$ ) for BT-BNT-xBMT at various frequencies showed that phase transition of ceramics changed from ferroelectric to relaxor-like behavior as BMT content increased. Furthermore, remanent polarization ( $P_r$ ), coercive field ( $E_c$ ) and the normalized strain ( $d_{33}^*$ ) of BT-BNT-xBMT ceramics tend to decrease with increasing BMT concentration.*

## 1. Introduction

Lead zirconate titanate (PZT) ceramics have been used widely in many electronic devices such as piezoelectric sensor, actuators and transducers because of their excellence

piezoelectric properties [1]. However, PZT-based piezoelectric ceramics are not environmental friendly because more than 60% wt of these ceramics contains the lead toxicity. Furthermore, the EU legislation forced draft directives including Waste from Electrical and Electronic Equipment (WEEE) and Restriction of Hazardous Substances (RoHS). According to the environmental issues, lead free friendly piezoelectric ceramics have been received considerable attentions to replace lead-based piezoelectric materials.

Although no real lead free materials can be replaced the common use in lead-based ceramics for various applications, many potentially promising lead free materials have been developed. Among the lead free materials, Barium titanate ( $\text{BaTiO}_3$ ; BT) has perovskite structure and good electrical properties such as ferroelectric and piezoelectric properties but low Curie temperature ( $T_c$ ) [2]. In recent years, there are many researches about BT-base for example  $\text{Ba}_{0.85}\text{Ca}_{0.15}\text{Ti}_{0.90}\text{Zr}_{0.10}\text{O}_3$  [3] and  $(1-x)\text{Ba}_{0.98}\text{Ca}_{0.02}\text{Ti}_{0.94}\text{Sn}_{0.06}\text{O}_3-x\text{Ba}_{0.85}\text{Ca}_{0.15}\text{Ti}_{0.90}\text{-Zr}_{0.10}\text{O}_3$  [4]. Jiagang Wu *et al.* [4] found that BT-base ceramic by combining  $(1-x)\text{Ba}_{0.98}\text{Ca}_{0.02}\text{Ti}_{0.94}\text{Sn}_{0.06}\text{O}_3-x\text{Ba}_{0.85}\text{Ca}_{0.15}\text{Ti}_{0.90}\text{Zr}_{0.10}\text{O}_3((1-x)\text{BCTS}-x\text{BCTZ})$  system has a phase boundary coexistence of orthorhombic and tetragonal phase at around 4 mol% BCTZ which show good dielectric and piezoelectric properties of dielectric constant ( $\epsilon_r \sim 5500$ ), dielectric loss ( $\tan\delta \sim 0.3\%$ ) and piezoelectric constant ( $d_{33} \sim 407$  pC/N). The binary system of  $\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3$ - $\text{BaTiO}_3$  (BNT-BT) is an important candidate for replacing lead-based piezoelectric. In a few decades, BNT-BT solid solution was studied by various research groups [2, 5, 6]. Takenaka *et al.* [5] found that BNT-BT system has a morphotropic phase boundary (MPB) between rhombohedral and tetragonal phases at around 6-7 mol% BT which shows the excellent properties including  $\epsilon_{33}^T/\epsilon_0 = 580$ , piezoelectric constant ( $d_{33} = 125$  pC/N), Curie temperature ( $T_c = 288^\circ\text{C}$ ), dielectric loss ( $\tan\delta = 1.3\%$ ) and planar coupling coefficient ( $k_{33} = 55.0\%$ ). Afterwards, researchers focused to develop BNT-BT binary material on the composition range of MPB by doing ternary solid solution such as KNN-modified BNT-BT [7,8] and BZr-modified BNT-BT [9]. Also, the BNT-BT-based systems on the BNT-rich side have been investigated extensively for example  $(0.94-x)\text{BNT}-0.06\text{BT}-x\text{KNN}$  [7],  $0.865\text{BNT}-0.350\text{BT}-0.100\text{BKT}$  [8] and BZr-modified BNT-BT [9]. However, few works have investigated and developed BNT-BT on the BT-rich side. Recently, Wada *et al.* studied on the combination between  $\text{BaTiO}_3$  and  $\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  (BMT) and found that BMT can enhance Curie temperature ( $T_c$ ) of BT with the highest  $T_c$  (about  $360^\circ\text{C}$ ) for  $0.5\text{BaTiO}_3$ - $0.5\text{BMT}$  ceramics [10]. Moreover, Qi Wang *et al.* have studied lead free  $\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3$ - $\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  systems and reported that BMT can improve piezoelectric properties and enhance  $T_c$  of BNT ceramic. The  $0.95\text{BNT}-0.05\text{BMTO}_3$  ceramic showed the highest  $d_{33}$  about 110pC/N and high  $T_c$  at  $352^\circ\text{C}$  [11].

This work dealt with the new ternary system of  $0.9\text{BaTiO}_3$ - $(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3$ - $x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  (BT-BNT- $x$ BMT) in order to get more information of BT-BNT-based on BT-rich side. BT-BNT- $x$ BMT ceramics were prepared by the solid state reaction. The effect of BMT on crystal structure, phase transition and electrical properties were studied as a function of composition,  $x$ .

## 2. Experimental

Lead free  $0.9\text{BaTiO}_3$ - $(0.1-x)\text{Bi}_{0.5}\text{Na}_{0.5}\text{TiO}_3$ - $x\text{Bi}(\text{Mg}_{0.5}\text{Ti}_{0.5})\text{O}_3$  (BT-BNT- $x$ BMT) ceramics, where  $x = 0.00, 0.02, 0.04, 0.06, 0.08, 0.10$ , were synthesized by the solid state reaction.  $\text{Bi}_2\text{O}_3$  (99.9%, Sigma-Aldrich),  $\text{BaCO}_3$  (98.5%, Fluka),  $\text{Na}_2\text{CO}_3$  (99.8%, Riedel-deHaen),  $\text{TiO}_2$  (99.9%, Sigma-Aldrich) and  $\text{MgO}$  (99%, Fluka) powders were used raw materials. First, stoichiometric amounts of raw materials were weighted and ball-milled with yttrium-stabilized zirconia in ethanol media for 18 hours. After drying the mixture for 24 h in an oven, the mixed

powder was calcined at 900°C for 4 hours with heating/cooling rate 10°C/min. In order to obtain fine particles prior to making a pellet, the calcined powders were ground and sieved. The fine powders were pressed into disks with 15 mm diameter. 5 wt% polyvinyl alcohol as a binder was used as binder. The disks were sintered at 1150-1250°C for 4 hours with heating/cooling rate 5°C/min. The crystal structure of ceramics was characterized using X-ray diffraction (Bruker-AXS D 8 Advance) with  $\text{Cu}(\text{K}\alpha)$  radiation in the  $2\theta$  scan range of 20°–80°. For electrical measurements, the samples were polished for both sides and made parallel before electrode coating with silver paste (C1000, Heraeus) on both surfaces. Silver paste was heated on at 750°C for 20 min with heating/cooling rate 5°C/min. The relative permittivity ( $\epsilon_r$ ) and dielectric loss ( $\tan\delta$ ) were determined as a function of frequency (1-100 kHz) and temperature (room temperature to 250°C) using LCR meter (HP4284A, Hewlett-Packard, Palo Alto, CA). Polarization-electric field (P-E) hysteresis loop were determined at room temperature using Radiant Technologies, Inc (RT66A). The strain-electric field (S-E) curves were determined using MTI-2100 Fotonic sensor combined with Radiant Technologies. The peak field for P-E hysteresis loop and S-E curve measurements was maintained at 60 kV/cm during measurement. The surface morphology of ceramics was observed using scanning electron microscope (EVO<sup>®</sup>MA10).

### 3. Results and Discussion

The X-ray diffraction patterns of BT-BNT- $x$ BMT ceramics, where  $x = 0.00, 0.02, 0.04, 0.06, 0.08, 0.1$ , are shown in Figure 1(a). It indicates that all samples are a single phase with the perovskite structure. The secondary and other phases were not observed in the XRD patterns, which indicating that all compositions in the BT-BNT- $x$ BMT system can completely form solid solution with a perovskite structure. A (111) peak at around 39 was chosen to identify the crystal structure of BT-BNT- $x$ BMT ceramics as shown in Figure 1(b). In the compositions,  $0.00 \leq x \leq 0.08$ , the crystal structure has a tetragonal symmetry, identified by a splitting of the (002) and (200) peaks. At the higher BMT content of  $x = 0.1$ , the doublet of (002) and (200) peaks become a single peak of (200) and the (111) peak still exhibits a single peak. These results indicated that the crystal structure changed to a pseudocubic symmetry.

The average ionic radius of A-site and B-site, calculated lattice parameters, the tetragonality  $c/a$  ratio and tolerance factor of each composition are listed in Table 1. The tetragonality  $c/a$  ratio is the important factor representing the lattice distortion of the tetragonal symmetry. It is seen that the  $c/a$  ratio decreases significantly with increasing BMT content. The ionic radii of  $\text{Bi}^{3+}$  (CN = 12, 1.40 Å) are smaller than the ionic radii of  $\text{Ba}^{2+}$  (CN = 12, 1.61 Å) resulting in the decreasing of average ionic radii at A-site [12]. Also, the substitution of  $\text{Ti}^{4+}$  ions (CN = 6, 0.605 Å) by  $\text{Mg}^{2+}$  (CN = 6, 0.72 Å) results in the increasing of average ionic radii at B-site as shown in Table 1. Then, it is reasonable to assume that the substitution of BMT into BT-BNT leads to the distortion and deformation of tetragonal structure. Furthermore, the tolerance factor ( $t$ ) is important factor that reflecting the perovskite structure distortion, rotation and tilt of the  $\text{BO}_6$  octahedra [13]. Generally, the perovskite structure is stable in the range of  $0.880 < t < 1.090$  region [14] and the symmetry is higher as the  $t$  value is approach to 1. It is also noticed that the  $t$  for BT-BNT- $x$ BMT ceramics tends to decrease with increasing BMT which corresponds well with the phase transition from tetragonal to pseudocubic symmetry.

Based on the XRD data, it could be said that the combination between BT-BNT and BMT could form completely crystalline solid solution of perovskite structure but the existence of BMT caused the tetragonality of BT-BNT decrease.

**Figure 1.** (a) X-ray diffraction patterns of 0.9BT-(0.1-x)BNT-(x)BMT ceramics with the composition  $0.00 \leq x \leq 0.10$ ; (b) X-ray diffraction patterns for (111), (002) and (200) peaks of 0.9BT-(0.1-x)BNT-(x)BMT ceramics with the composition  $0.00 \leq x \leq 0.10$ .

Figure 2 illustrates the temperature dependence of the relative permittivity ( $\epsilon_r$ ) and dielectric loss ( $\tan\delta$ ) of BT-BNT-xBMT ceramics measured at various frequencies between 1 and 100 kHz. Regarding the composition,  $x = 0.00$ , the relative permittivity of 0.9BT-0.1BNT increased slowly until the temperature approached transition temperature, then it abruptly increased and passed through a maximum of about 178°C. This discontinuity of dielectric constant at phase transition is characteristic of the first order phase transition [15] and occurs from the change of the tetragonal ferroelectric (FE) phase into the cubic paraelectric (PE) phase, in agreement with previous reports [2]. The relative permittivity curves at the compositions,  $0.02 \leq x \leq 0.10$ , showed only one phase transition. The composition,  $x = 0.02$ , showed a broadening dielectric peak which much like the characteristic of relaxor ferroelectric, however the position of the peaks keep unchanged at various applied frequency. At higher composition,  $0.04 \leq x \leq 0.10$ , the diffuse phase transition behaviour with broad maximum and frequency dispersion became more self-evident when BMT concentration increased. Also, the transition temperature is dependent of frequency and increases with increasing frequency. These results indicated that BT-BNT-xBMT progressively change from normal ferroelectric to relaxor ferroelectric when

0.04	T	1.5902	0.6073	1.0534	$3.9792 \pm 0.0500$	$4.0675 \pm 0.1641$	1.0222
0.06	T	1.5898	0.6085	1.0526	$3.9969 \pm 0.0421$	$4.0282 \pm 0.0456$	1.0078
0.08	T	1.5894	0.6096	1.0519	$4.0017 \pm 0.0159$	$4.0131 \pm 0.0118$	1.0029
0.10	PC	1.5890	0.6107	1.0511	$4.0066 \pm 0.0049$	–	–

**Figure 2.** Relative permittivity ( $\epsilon_r$ ) and dielectric loss ( $\tan\delta$ ) as a temperature dependence of 0.9BT-(0.1-x)BNT-(x)BMT ceramics with the composition  $0.00 \leq x \leq 0.10$ .

BMT concentration increases. This phenomenon of BT-BNT- $x$ BMT system resulted from the substitutions of  $\text{Bi}^{3+}$  ions for  $\text{Na}^+$  ions and  $\text{Mg}^{2+}$  ions for  $\text{Ti}^{4+}$ , which distort the unit cell and change dipole moment. For complex perovskite compound, the more cations occupy the equivalent crystallographic site of A or B, the more the chemical fluctuation and structural disorder in arrangement of cations are inhomogeneous at the nanometre scale, then the relaxation characteristic becomes more distinctly [16, 17].

In order to further characterize the relaxor behavior, a modified Curie-Weiss law in equation (1) was used for description a broad relative permittivity and diffuseness of phase transition [18, 19].

$$\frac{\epsilon_m}{\epsilon} = 1 + \frac{(T - T_m)^\gamma}{2\delta_\gamma} \quad (1)$$

where  $\epsilon_m$  is the maximum value of relative permittivity and  $T_m$  is the temperature of dielectric maximum. The  $\gamma$  value expresses the degree of dielectric relaxation in relaxor

**Figure 3.** The relative plot between  $\ln(1/\epsilon - 1/\epsilon_m)$  and  $\ln(T - T_m)$ .

ferroelectric material which this value is in the range of  $1 \leq \gamma \leq 2$ . When  $\gamma$  value is equal 1, Eq. (1) becomes the classic Curie Weiss law valid in the case of normal ferroelectric. When  $\gamma$  value is equal 1, the ideal relaxor behavior with quadratic dependence is described. The parameter  $\delta_\gamma$  is the diffuse parameter which can be used to determine the degree of diffuseness in the phase transition. The  $\delta_\gamma$  value can be observed from the slope of  $\epsilon'_m/\epsilon'$  versus  $(T-T_m)^2$ , which should be linear. Plot of  $\ln(\frac{1}{\epsilon} - \frac{1}{\epsilon_m})$  as function of  $\ln(T-T_m)$  at 100 kHz of BT-BNT-xBMT ceramics are displayed in figure 3. By plotting  $\ln(1/\epsilon - 1/\epsilon_{max})$  versus  $\ln(T-T_m)$ , the  $\gamma$  value can be determined directly from the gradient. The  $\gamma$  and  $\delta_\gamma$  values are determined and shown in Table 2. It is clearly seen that both  $\delta_\gamma$  and  $\gamma$  values tend to increase with increasing of the BMT content, confirming the relaxor behavior in these solid solution. Based on the dielectric data, a slim P-E hysteresis loop in BT-BNT-xBMT ceramic at high BMT content is expected to observe at room temperature.

Curie temperature and maximum relative permittivity ( $\epsilon_{rmax}$ ) at 100 kHz of BT-BNT-xBMT ceramics are determined and plotted as a function of composition in

**Figure 4.** (a) The relative plot between Curie temperature and maximum relative permittivity ( $\epsilon_{r\max}$ ) as a function of composition ( $x$ ); (b) The relative plot between relative permittivity at room temperature ( $\epsilon_{r\text{room}}$ ) and dielectric loss ( $\tan\delta$ ) as a function of composition ( $x$ ).

Figure 4(a). It was observed that Curie temperature decreased rapidly with further increase of BMT. As the previous works have reported that the rapidly decrease in transition can be caused by valence mismatch [20, 21]. In BT-BNT- $x$ BMT system, the differences in valence of ions at A-site ( $\text{Ba}^{2+}$ ,  $\text{Na}^{+}$ ,  $\text{Bi}^{3+}$ ) and B-site ( $\text{Mg}^{2+}$ ,  $\text{Ti}^{4+}$ ) might be result in valance mismatch, thus Curie temperature decrease with increasing BMT content. Similar behavior is also observed for the substitution of BMT in KNN structure [22]. Moreover, the maximum relative permittivity ( $\epsilon_{r\max}$ ) of BT-BNT- $x$ BMT ceramics tends to decrease with increasing BMT concentration. However, at room temperature the relative permittivity ( $\epsilon_{r\text{room}}$ ) tends to abruptly increase with increasing BMT, excepting the composition,  $x = 0.10$ . While, dielectric loss ( $\tan\delta$ ) tend to gradually increase with BMT increase as shown in Figure 4(b). The smooth increase of  $\epsilon_{r\text{room}}$  for the compositions,  $0.02 \leq x \leq 0.08$ , might be attributed to the decreasing of Curie temperature to room temperature. While, the  $\epsilon_{r\text{room}}$  of composition,  $x = 0.10$  is decrease might be the Curie temperature being below room temperature.

The composition dependence of polarization-electric field (P-E) hysteresis loops for BT-BNT- $x$ BMT system was measured at room temperature with electric field of 60 kV/cm, as shown in figure 5. It is evident that all ceramics display the saturated P-E

**Figure 5.** The relative plot of polarization ( $\mu\text{C}/\text{cm}^2$ ) with electric field (kV/cm) of 0.9BT-(0.1-x)BNT-(x)BMT ( $x = 0.00$ -0.10) ceramics.

hysteresis loops. For 0.9BT-0.1BNT, a shape of hysteresis loop displays typically normal ferroelectric behavior with remanent polarization ( $P_r$ ) and coercive field ( $E_c$ ) of  $15.52 \mu\text{C}/\text{cm}^2$  and  $29.47 \text{ kV}/\text{cm}$ , respectively, which in good agreement with previous work [2]. Normal ferroelectric contains a long-range interaction between dipoles in the ferroelectric micro-domain state, giving a typical square hysteresis loops with high  $P_r$  and  $E_c$ . As expected for BT-BNT-xBMT ceramics, the substitution of BMT has significantly effect on the hysteresis loops shape and polarization and coercive field values. The more BMT concentration increases, the more the hysteresis loop shape becomes slim, identified the gradually drop of  $P_r$ ,  $P_s$  and  $E_c$  values as summarized in Table 2. This result suggests that the long-range order of polarization in ferroelectric micro-domain was significantly broken down to polar nano-regions by adding BMT. Then, at high content of BMT, normal ferroelectric BT-BNT-xBMT ceramics become relaxor-like behavior exhibiting a slim P-E hysteresis loop with low  $P_r$  and  $E_c$ . For low content of BMT, the decreasing of  $P_r$  and  $E_c$  might be due to an easier of domain switching and domain wall motions [23] as well as tetragonality decreasing of crystal structure in this system [24]. The plots of  $P_r$  and  $E_c$  values against composition are given in figure 6. Again, a clearly smooth trend of decrease was seen in  $P_r$  and  $E_c$  with respect to BMT content, confirming the completely solid solution formation in BT-BNT-xBMT system.

To confirm the changes in hysteresis behavior, the empirical relationship between  $P_r$ ,  $P_s$  and polarization at fields above the  $E_c$  proposed by Haertling and Zimmer was used for calculated the squareness of hysteresis loop [25]

$$R_{sq} = \frac{P_r}{P_s} + \frac{P_{1.1EC}}{P_r} \quad (2)$$

where  $R_{sq}$ ,  $P_r$  and  $P_s$  are squareness of hysteresis loop, remanent polarization and saturation polarization, respectively.  $P_{1.1EC}$  is the polarization at an electric field equal to 1.1 times the coercive field ( $E_c$ ). The squareness parameter reflects the quantification of changes P-E hysteresis loops. For an ideal P-E hysteresis loops, the  $R_{sq}$  is equal to 2. The calculated  $R_{sq}$  for all ceramics is listed in Table 2. It is clearly found that, as BMT content

**Figure 6.** The composition ( $x$ ) dependence of remanent polarization ( $P_r$  ( $\mu\text{C}/\text{cm}^2$ )) and coercive field ( $E_c$  (kV/cm)) in 0.9BT-(0.1-x)BNT-(x)BMT ceramics.

increase, the  $R_{sq}$  parameter decreases from 1.56 to 0.33 which implies that P-E hysteresis loop becomes more slanted. On the other words, the P-E loops changes from normal ferroelectric to relaxor behavior with increasing BMT concentration which is consistent with the dielectric result.

Combined with the ferroelectric, the dielectric and XRD results of BT-BNT- $x$ BMT ceramic, all of changes such as the transformation of crystal structure, the decreasing of transition temperature and remanent polarization and ferroelectric – relaxor ferroelectric phase transition are so smooth. Therefore, it could be said that BT-BNT and BMT can completely form solid solution throughout the whole composition range.

Figure 7 illustrates the unipolar strain curves of BT-BNT- $x$ BMT ceramics measured at room temperature with an external electric field of 60 kV/cm. It is clearly found the decreasing of unipolar strain of BT-BNT- $x$ BMT ceramics from 0.2% to 0.09% when the

**Figure 7.** The relative plot of unipolar strain (%) as a function of electric field (kV/cm) in 0.9BT-(0.1-x)BNT-(x)BMT ( $x = 0.00-0.10$ ) ceramics.

**Figure 8.** Normalized strain ( $d_{33}^*$  (pm/V)) value of  $0.9\text{BT}-(0.1-x)\text{BNT}-(x)\text{BMT}$  ceramics with the composition  $0.00 \leq x \leq 0.10$ .

composition of  $x$  was increased from 0.00 to 0.10. The normalized strain ( $d_{33}^*$ ) value of BT-BNT-XBMT ceramics was calculated from the  $S_{\max}/E_{\max}$  ratio for each composition. The composition dependence of normalized strain tends to decrease from 328 pm/V to 153 pm/V when composition of BMT increases, as represented in figure 8. This result has caused the approaching to the relaxor-like behavior with increasing of BMT [26].

**Figure 9.** SEM micrographs of  $0.9\text{BT}-(0.1-x)\text{BNT}-(x)\text{BMT}$  ceramics with various compositions (a)  $x = 0.00$ , (b)  $x = 0.02$ , (c)  $x = 0.04$ , and (d)  $x = 0.10$ .

The composition dependence of the level of induce strain is similar to result observation of BT-Bi(Ni<sub>1/2</sub>Ti<sub>1/2</sub>)O<sub>3</sub> system [27].

Figure 9 displays SEM micrograph of the sintered surfaces of BT-BNT-*x*BMT ceramics at *x* = 0.00, 0.02, 0.04 and 0.10. The substitution of BMT directly effects on the average grain size of BT-BNT-*x*BMT ceramics. For the composition *x* = 0.00, the grain morphology shows and the average grain size is about 1.01 ± 0.14 μm. Homogeneous and uniformity feature microstructures were observed in the composition *x* = 0.00. The wide grain size distributions was observed in the composition *x* = 0.02 and 0.04. For the composition *x* = 0.10, more disorderly and unsystematic shaped grains are observed. A dramatic grain growth inhibition was founded with increasing BMT composition. The average grain size decreased significantly with increasing the composition *x*. The average grain size are about 0.72 ± 0.09 μm, 0.54 ± 0.09 μm, and 0.49 ± 0.07 μm for the composition *x* = 0.02, 0.04 and 0.10 respectively. This should be attributed to the effects arisen from the donor-type nature of BMT on inhibiting the grain growth [22]. The decreasing in piezoelectric properties in BNT-BT-*x*BMT system may be attributed to the inhibiting of the grain growth coursed by substitution of BMT in the BNT-BT system. The detailed mechanisms of the diminution in piezoelectric properties of BNT-BT-*x*BMT system are unclear and demands further study.

#### 4. Conclusion

Lead free 0.9BaTiO<sub>3</sub>-(0.1-*x*)Bi<sub>0.5</sub>Na<sub>0.5</sub>TiO<sub>3</sub>-*x*Bi(Mg<sub>0.5</sub>Ti<sub>0.5</sub>)O<sub>3</sub> (BT-BNT-*x*BMT; *x* = 0.00 – 0.10) piezoelectric ceramics were synthesized successfully by the solid state reaction. The crystal structure of BT-BNT-*x*BMT solid solution transforms from tetragonal to pseudocubic symmetry with increasing of BMT content. Combined with the ferroelectric and the dielectric results of BT-BNT-*x*BMT ceramic, phase transition of ceramics gradually changed from ferroelectric to relaxor-like behavior as BMT content increased. Also, BT-BNT and BMT can completely form solid solution throughout the whole composition range.
